This research was supported under the auspices of the U.S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under contract No. W-7405-Eng-48.

Contents

1 Introduction

SUNDIALS [2], SUite of Nonlinear and DIfferential/ALgebraic equation Solvers, is a family of software tools for integration of ODE and DAE initial value problems and for the solution of nonlinear systems of equations. It consists of CVODE, IDA, and KINSOL, and variants of these with sensitivity analysis capabilities.

SUNDIALSTB is a collection of MATLAB functions which provide interfaces to the SUNDIALS solvers.

The core of each MATLAB interface in SUNDIALSTB is a single MEX file which interfaces to the various user-callable functions for that solver. However, this MEX file should not be called directly, but rather through the user-callable functions provided for each MATLAB interface.

A major design principle for SUNDIALSTB was to provide an interface that is, as much as possible, equally familiar to both SUNDIALS users and MATLAB users. Moreover, we tried to keep the number of user-callable functions to a minimum. For example, the CVODES MATLAB interface contains only 12 such functions, 2 of which relate to forward sensitivity analysis and 4 more interface solely to the adjoint sensitivity module in CVODES. A user who is only interested in integration of ODEs and not in sensitivity analysis therefore needs to call at most 6 functions. In tune with the MATLAB ODESET function, optional solver inputs in SUNDIALSTB are specified through a single function; e.g. `CvodeSetOptions` for CVODES (a similar function is used to specify optional inputs for forward sensitivity analysis). However, unlike the ODE solvers in MATLAB, we have kept the more flexible SUNDIALS model in which a separate "solve" function (`CVodeSolve` for CVODES) must be called to return the solution at a desired output time. Solver statistics, as well as optional outputs (such as solution and solution derivatives at additional times) can be obtained at any time with calls to separate functions (`CVodeGetStats` and `CVodeGet` for CVODES).

This document provides a complete documentation for the SUNDIALSTB functions. For additional details on the methods and underlying SUNDIALS software consult also the coresponding SUNDIALS user guides [3, 1].

1.1 Notes

The version numbers for the MATLAB interfaces correspond to those of the corresponding SUNDIALS solver with wich the interface is compatible.

1.2 Requirements

Each interface module in SUNDIALSTB requires the appropriate version of the corresponding SUNDIALS solver. For parallel support, SUNDIALSTB depends on MPITB with LAM v $>$ 7.1.1 (for MPI-2 spawning feature).

1.3 Installation/Setup

The following steps are required to install and setup SUNDIALSTB:

1.3.1 Compilation and installation of sundialsTB

As of version 2.3.0, SUNDIALSTB is distributed only with the complete SUNDIALS package and, on *nix systems (or under cygwin in Windows), the MATLAB toolbox can be configured, built, and installed using the main SUNDIALS configure script. For details see the SUNDIALS file `INSTALL_NOTES`.

For systems that do not support configure scripts (or if the configure script fails to configure SUNDIALSTB), we provide a MATLAB script (`install_STB.m`) which can be used to build and install SUNDIALSTB from within MATLAB. In the sequel, we assume that the SUNDIALS package was unpacked under the directory *srcdir*. The SUNDIALSTB files are therefore in *srcdir*`/sundialsTB`.

To facilitate the compilation of SUNDIALSTB on platforms that do not have a make system, we rely on MATLAB's mex command. Compilation of SUNDIALSTB is done by running from under MATLAB the `install_STB.m` script which is present in the SUNDIALSTB top directory.

1. Launch matlab in sundialsTB

   ```
   % cd srcdir/sundialsTB
   % matlab
   ```

2. Run the install_STB matlab script

   Note that parallel support will be compiled into the MEX files only if $LAMHOME is defined **and** $MPITB_ROOT is defined **and** *srcdir*/src/nvec_par exists.

   After the MEX files are generated, you will be asked if you wish to install the SUNDIALSTB toolbox. If you answer yes, you will be then asked for the installation directory (called in the sequel *instdir*). To install SUNDIALSTB for all MATLAB users (not usual), assuming MATLAB is installed under `/usr/local/matlab7`, specify *instdir* = `/usr/local/matlab7/toolbox`. To install SUNDIALSTB for just one user (usual configuration), install SUNDIALSTB under a directory of your choice (typically under your `matlab` working directory). In other words, specify *instdir* = `/home/user/matlab`.

1.3.2 Configuring Matlab's startup

After a successful installation, a SUNDIALSTB.m startup script is generated in *instdir*/`sundialsTB`. This file must be called by MATLAB at initialization.

If SUNDIALSTB was installed for all MATLAB users (not usual), add the SUNDIALSTB startup to the system-wide startup file (by linking or copying):

```
% cd /usr/local/matlab7/toolbox/local
% ln -s ../sundialsTB/startup_STB.m .
```

and add these lines to your original local startup.m

```
% SUNDIALS Toolbox startup M-file, if it exists.
if exist('startup_STB','file')
   startup_STB
end
```

If SUNDIALSTB was installed for just one user (usual configuration) and assuming you do not need to keep any previously existing startup.m, link or copy the startup_STB.m script to your working 'matlab' directory:

```
% cd ~/matlab
% ln -s sundialsTB/startup_STB.m startup.m
```

If you already have a startup.m, use the method described above, first linking (or copying) `startup_STB.m` to the destination subdirectory and then editing the file `/matlab/startup.m` to run `startup_STB.m`.

1.3.3 Testing the installation

If everything went fine, you should now be able to try one of the CVODES, IDAS, or KINSOL examples (in matlab, type 'help cvodes', 'help idas', or 'help kinsol' to see a list of all examples available). For example, cd to the CVODES serial example directory:

```
% cd instdir/sundialsTB/cvode/examples_ser
```

and then launch matlab and execute cvdx.

1.4 Links

The required software packages can be obtained from the following addresses.

2 MATLAB Interface to CVODES

The MATLAB interface to CVODES provides access to all functionality of the CVODES solver, including IVP simulation and sensitvity analysis (both forward and adjoint).

The interface consists of 9 user-callable functions. The user must provide several required and optional user-supplied functions which define the problem to be solved. The user-callable functions and the types of user-supplied functions are listed in Table 1 and fully documented later in this section. For more in depth details, consult also the CVODES user guide [3].

To illustrate the use of the CVODES MATLAB interface, several example problems are provided with SUNDIALSTB, both for serial and parallel computations. Most of them are MATLAB translations of example problems provided with CVODES.

Table 1: CVODES MATLAB interface functions

Functions	CVodeSetOptions	creates an options structure for CVODES.
	CVodeSetFSAOptions	creates an options structure for FSA with CVODES.
	CVodeMalloc	allocates and initializes memory for CVODES.
	CVodeSensMalloc	allocates and initializes memory for FSA with CVODES.
	CVadjMalloc	allocates and initializes memory for ASA with CVODES.
	CVodeMallocB	allocates and initializes backward memory for CVODES.
	CVode	integrates the ODE.
	CVodeB	integrates the backward ODE.
	CVodeGetStats	returns statistics for the CVODES solver.
	CVodeGetStatsB	returns statistics for the backward CVODES solver.
	CVodeGet	extracts data from CVODES memory.
	CVodeFree	deallocates memory for the CVODES solver.
	CVodeMonitor	sample monitoring function.
Function types	CVRhsFn	RHS function
	CVRootFn	root-finding function
	CVQuadRhsFn	quadrature RHS function
	CVDenseJacFn	dense Jacobian function
	CVBandJacFn	banded Jacobian function
	CVJacTimesVecFn	Jacobian times vector function
	CVPrecSetupFn	preconditioner setup function
	CVPrecSolveFn	preconditioner solve function
	CVGlocalFn	RHS approximation function (BBDPre)
	CVGcommFn	communication function (BBDPre)
	CVSensRhsFn	sensitivity RHS function
	CVMonitorFn	monitoring function

2.1 Interface functions

CVodeSetOptions

PURPOSE

```
CVodeSetOptions creates an options structure for CVODES.
```

SYNOPSIS

```
function options = CVodeSetOptions(varargin)
```

DESCRIPTION

```
CVodeSetOptions creates an options structure for CVODES.

   Usage: OPTIONS = CVodeSetOptions('NAME1',VALUE1,'NAME2',VALUE2,...)
          OPTIONS = CVodeSetOptions(OLDOPTIONS,'NAME1',VALUE1,...)
          OPTIONS = CVodeSetOptions(OLDOPTIONS,NEWOPTIONS)

   OPTIONS = CVodeSetOptions('NAME1',VALUE1,'NAME2',VALUE2,...) creates
   a CVODES options structure OPTIONS in which the named properties have
   the specified values. Any unspecified properties have default values.
   It is sufficient to type only the leading characters that uniquely
   identify the property. Case is ignored for property names.

   OPTIONS = CVodeSetOptions(OLDOPTIONS,'NAME1',VALUE1,...) alters an
   existing options structure OLDOPTIONS.

   OPTIONS = CVodeSetOptions(OLDOPTIONS,NEWOPTIONS) combines an existing
   options structure OLDOPTIONS with a new options structure NEWOPTIONS.
   Any new properties overwrite corresponding old properties.

   CVodeSetOptions with no input arguments displays all property names
   and their possible values.

CVodeSetOptions properties
(See also the CVODES User Guide)

LMM - Linear Multistep Method [ 'Adams' | 'BDF' ]
   This property specifies whether the Adams method is to be used instead
   of the default Backward Differentiation Formulas (BDF) method.
   The Adams method is recommended for non-stiff problems, while BDF is
   recommended for stiff problems.
NonlinearSolver - Type of nonlinear solver used [ Functional | Newton ]
   The 'Functional' nonlinear solver is best suited for non-stiff
   problems, in conjunction with the 'Adams' linear multistep method,
   while 'Newton' is better suited for stiff problems, using the 'BDF'
   method.
RelTol - Relative tolerance [ positive scalar | 1e-4 ]
   RelTol defaults to 1e-4 and is applied to all components of the solution
   vector. See AbsTol.
AbsTol - Absolute tolerance [ positive scalar or vector | 1e-6 ]
```

```
   The relative and absolute tolerances define a vector of error weights
   with components
     ewt(i) = 1/(RelTol*|y(i)| + AbsTol)    if AbsTol is a scalar
     ewt(i) = 1/(RelTol*|y(i)| + AbsTol(i)) if AbsTol is a vector
   This vector is used in all error and convergence tests, which
   use a weighted RMS norm on all error-like vectors v:
     WRMSnorm(v) = sqrt( (1/N) sum(i=1..N) (v(i)*ewt(i))^2 ),
   where N is the problem dimension.
MaxNumSteps - Maximum number of steps [positive integer | 500]
   CVode will return with an error after taking MaxNumSteps internal steps
   in its attempt to reach the next output time.
InitialStep - Suggested initial stepsize [ positive scalar ]
   By default, CVode estimates an initial stepsize h0 at the initial time
   t0 as the solution of
     WRMSnorm(h0^2 ydd / 2) = 1
   where ydd is an estimated second derivative of y(t0).
MaxStep - Maximum stepsize [ positive scalar | inf ]
   Defines an upper bound on the integration step size.
MinStep - Minimum stepsize [ positive scalar | 0.0 ]
   Defines a lower bound on the integration step size.
MaxOrder - Maximum method order [ 1-12 for Adams, 1-5 for BDF | 5 ]
   Defines an upper bound on the linear multistep method order.
StopTime - Stopping time [ scalar ]
   Defines a value for the independent variable past which the solution
   is not to proceed.
RootsFn - Rootfinding function [ function ]
   To detect events (roots of functions), set this property to the event
   function. See CVRootFn.
NumRoots - Number of root functions [ integer | 0 ]
   Set NumRoots to the number of functions for which roots are monitored.
   If NumRoots is 0, rootfinding is disabled.
StabilityLimDet - Stability limit detection algorithm [ on | off ]
   Flag used to turn on or off the stability limit detection algorithm
   within CVODES. This property can be used only with the BDF method.
   In this case, if the order is 3 or greater and if the stability limit
   is detected, the method order is reduced.

LinearSolver - Linear solver type [Dense|Diag|Band|GMRES|BiCGStab|TFQMR]
   Specifies the type of linear solver to be used for the Newton nonlinear
   solver (see NonlinearSolver). Valid choices are: Dense (direct, dense
   Jacobian), Band (direct, banded Jacobian), Diag (direct, diagonal Jacobian),
   GMRES (iterative, scaled preconditioned GMRES), BiCGStab (iterative, scaled
   preconditioned stabilized BiCG), TFQMR (iterative, scaled transpose-free QMR).
   The GMRES, BiCGStab, and TFQMR are matrix-free linear solvers.
JacobianFn - Jacobian function [ function ]
   This propeerty is overloaded. Set this value to a function that returns
   Jacobian information consistent with the linear solver used (see Linsolver).
   If not specified, CVODES uses difference quotient approximations.
   For the Dense linear solver, JacobianFn must be of type CVDenseJacFn and
   must return a dense Jacobian matrix. For the Band linear solver, JacobianFn
   must be of type CVBandJacFn and must return a banded Jacobian matrix.
   For the iterative linear solvers, GMRES, BiCGStab, and TFQMR, JacobianFn must
   be of type CVJacTimesVecFn and must return a Jacobian-vector product. This
   property is not used for the Diag linear solver.
```

KrylovMaxDim - Maximum number of Krylov subspace vectors [integer | 5]
Specifies the maximum number of vectors in the Krylov subspace. This property is used only if an iterative linear solver, GMRES, BiCGStab, or TFQMR is used (see LinSolver).

GramSchmidtType - Gram-Schmidt orthogonalization [Classical | Modified]
Specifies the type of Gram-Schmidt orthogonalization (classical or modified). This property is used only if the GMRES linear solver is used (see LinSolver).

PrecType - Preconditioner type [Left | Right | Both | None]
Specifies the type of user preconditioning to be done if an iterative linear solver, GMRES, BiCGStab, or TFQMR is used (see LinSolver). PrecType must be one of the following: 'None', 'Left', 'Right', or 'Both', corresponding to no preconditioning, left preconditioning only, right preconditioning only, and both left and right preconditioning, respectively.

PrecModule - Preconditioner module [BandPre | BBDPre | UserDefined]
If PrecModule = 'UserDefined', then the user must provide at least a preconditioner solve function (see PrecSolveFn)
CVODES provides the following two general-purpose preconditioner modules:
BandPre provide a band matrix preconditioner based on difference quotients of the ODE right-hand side function. The user must specify the lower and upper half-bandwidths through the properties LowerBwidth and UpperBwidth, respectively.
BBDPre can be only used with parallel vectors. It provide a preconditioner matrix that is block-diagonal with banded blocks. The blocking corresponds to the distribution of the dependent variable vector y among the processors. Each preconditioner block is generated from the Jacobian of the local part (on the current processor) of a given function g(t,y) approximating f(t,y) (see GlocalFn). The blocks are generated by a difference quotient scheme on each processor independently. This scheme utilizes an assumed banded structure with given half-bandwidths, mldq and mudq (specified through LowerBwidthDQ and UpperBwidthDQ, respectively). However, the banded Jacobian block kept by the scheme has half-bandwiths ml and mu (specified through LowerBwidth and UpperBwidth), which may be smaller.

PrecSetupFn - Preconditioner setup function [function]
If PrecType is not 'None', PrecSetupFn specifies an optional function which, together with PrecSolve, defines left and right preconditioner matrices (either of which can be trivial), such that the product P1*P2 is an aproximation to the Newton matrix. PrecSetupFn must be of type CVPrecSetupFn.

PrecSolveFn - Preconditioner solve function [function]
If PrecType is not 'None', PrecSolveFn specifies a required function which must solve a linear system Pz = r, for given r. PrecSolveFn must be of type CVPrecSolveFn.

GlocalFn - Local right-hand side approximation funciton for BBDPre [function]
If PrecModule is BBDPre, GlocalFn specifies a required function that evaluates a local approximation to the ODE right-hand side. GlocalFn must be of type CVGlocFn.

GcommFn - Inter-process communication function for BBDPre [function]
If PrecModule is BBDPre, GcommFn specifies an optional function to perform any inter-process communication required for the evaluation of GlocalFn. GcommFn must be of type CVGcommFn.

LowerBwidth - Jacobian/preconditioner lower bandwidth [integer | 0]
This property is overloaded. If the Band linear solver is used (see LinSolver), it specifies the lower half-bandwidth of the band Jacobian approximation. If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used (see LinSolver) and if the BBDPre preconditioner module in CVODES is used

```
   (see PrecModule), it specifies the lower half-bandwidth of the retained
   banded approximation of the local Jacobian block. If the BandPre preconditioner
   module (see PrecModule) is used, it specifies the lower half-bandwidth of
   the band preconditioner matrix. LowerBwidth defaults to 0 (no sub-diagonals).
UpperBwidth - Jacobian/preconditioner upper bandwidth [ integer | 0 ]
   This property is overloaded. If the Band linear solver is used (see LinSolver),
   it specifies the upper half-bandwidth of the band Jacobian approximation.
   If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver) and if the BBDPre preconditioner module in CVODES is used
   (see PrecModule), it specifies the upper half-bandwidth of the retained
   banded approximation of the local Jacobian block. If the BandPre
   preconditioner module (see PrecModule) is used, it specifies the upper
   half-bandwidth of the band preconditioner matrix. UpperBwidth defaults to
   0 (no super-diagonals).
LowerBwidthDQ - BBDPre preconditioner DQ lower bandwidth [ integer | 0 ]
   Specifies the lower half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).
UpperBwidthDQ - BBDPre preconditioner DQ upper bandwidth [ integer | 0 ]
   Specifies the upper half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).

Quadratures - Quadrature integration [ on | off ]
   Enables or disables quadrature integration.
QuadRhsFn - Quadrature right-hand side function [ function ]
   Specifies the user-supplied function to evaluate the integrand for
   quadrature computations. See CVQuadRhsfn.
QuadInitCond - Initial conditions for quadrature variables [ vector ]
   Specifies the initial conditions for quadrature variables.
QuadErrControl - Error control strategy for quadrature variables [ on | off ]
   Specifies whether quadrature variables are included in the error test.
QuadRelTol - Relative tolerance for quadrature variables [ scalar 1e-4 ]
   Specifies the relative tolerance for quadrature variables. This parameter is
   used only if QuadErrCon=on.
QuadAbsTol - Absolute tolerance for quadrature variables [ scalar or vector 1e-6 ]
   Specifies the absolute tolerance for quadrature variables. This parameter is
   used only if QuadErrCon=on.

ASANumDataPoints - Number of data points for ASA [ integer | 100 ]
   Specifies the (maximum) number of integration steps between two consecutive
   check points.
ASAInterpType - Type of interpolation [ Polynomial | Hermite ]
   Specifies the type of interpolation used for estimating the forward solution
   during the backward integration phase. At this time, the only option is
   'Hermite', specifying cubic Hermite interpolation.

MonitorFn - User-provied monitoring function [ function ]
   Specifies a function that is called after each successful integration step.
   This function must have type CVMonitorFn. A simple monitoring function,
   CVodeMonitor is provided with CVODES.
MonitorData - User-provied data for the monitoring function [ struct ]
   Specifies a data structure that is passed to the Monitor function every time
   it is called.

ErrMessages - Turn on/off display of error/warning messages [ on | off ]
```

```

CVodeSetFSAOptions

Purpose

```
CVodeSetFSAOptions creates an options structure for FSA with CVODES.
```

Synopsis

```
function options = CVodeSetFSAOptions(varargin)
```

Description

```
CVodeSetFSAOptions creates an options structure for FSA with CVODES.

   Usage: OPTIONS = CVodeSetFSAOptions('NAME1',VALUE1,'NAME2',VALUE2,...)
          OPTIONS = CVodeSetFSAOptions(OLDOPTIONS,'NAME1',VALUE1,...)
          OPTIONS = CVodeSetFSAOptions(OLDOPTIONS,NEWOPTIONS)

   OPTIONS = CVodeSetFSAOptions('NAME1',VALUE1,'NAME2',VALUE2,...) creates
   a CVODES options structure OPTIONS in which the named properties have
   the specified values. Any unspecified properties have default values.
   It is sufficient to type only the leading characters that uniquely
   identify the property. Case is ignored for property names.

   OPTIONS = CVodeSetFSAOptions(OLDOPTIONS,'NAME1',VALUE1,...) alters an
   existing options structure OLDOPTIONS.

   OPTIONS = CVodeSetFSAOptions(OLDOPTIONS,NEWOPTIONS) combines an existing
   options structure OLDOPTIONS with a new options structure NEWOPTIONS.
   Any new properties overwrite corresponding old properties.

   CVodeSetFSAOptions with no input arguments displays all property names
   and their possible values.

CVodeSetFSAOptions properties
(See also the CVODES User Guide)

ParamField - Problem parameters  [ string ]
   Specifies the name of the field in the user data structure (passed as an
   argument to CVodeMalloc) in which the nominal values of the problem
   parameters are stored. This property is used only if  CVODES will use difference
   quotient approximations to the sensitivity right-hand sides (see SensRhsFn).
ParamList - Parameters with respect to which FSA is performed [ integer vector ]
   Specifies a list of Ns parameters with respect to which sensitivities are to
   be computed. This property is used only if CVODES will use difference-quotient
   approximations to the sensitivity right-hand sides (see SensRhsFn below).
```

```
   Its length must be Ns, consistent with the number of columns of yS0
   (see CVodeSensMalloc).
ParamScales - Order of magnitude for problem parameters [ vector ]
   Provides order of magnitude information for the parameters with respect to
   which sensitivities are computed. This information is used if CVODES
   approximates the sensitivity right-hand sides (see SensRhsFn below) or if CVODES
   estimates integration tolerances for the sensitivity variables (see SensReltol
   and SensAbsTol).
SensRelTol - Relative tolerance for sensitivity variables [ positive scalar ]
   Specifies the scalar relative tolerance for the sensitivity variables.
   See also SensAbsTol.
SensAbsTol - Absolute tolerance for sensitivity variables [ row-vector or matrix ]
   Specifies the absolute tolerance for sensitivity variables. SensAbsTol must be
   either a row vector of dimension Ns, in which case each of its components is
   used as a scalar absolute tolerance for the coresponding sensitivity vector,
   or a N x Ns matrix, in which case each of its columns is used as a vector
   of absolute tolerances for the corresponding sensitivity vector.
   By default, CVODES estimates the integration tolerances for sensitivity
   variables, based on those for the states and on the order of magnitude
   information for the problem parameters specified through ParamScales.
SensErrControl - Error control strategy for sensitivity variables [ on | off ]
   Specifies whether sensitivity variables are included in the error control test.
   Note that sensitivity variables are always included in the nonlinear system
   convergence test.
SensRhsFn - Sensitivity right-hand side function [ function ]
   Specifies a user-supplied function to evaluate the sensitivity right-hand
   sides. If not specified, CVODES uses a default internal difference-quotient
   function to approximate the sensitivity right-hand sides.
SensDQtype - Type of DQ approx. of the sensi. RHS [Centered | Forward ]
   Specifies whether to use centered (second-order) or forward (first-order)
   difference quotient approximations of the sensitivity eqation right-hand
   sides. This property is used only if a user-defined sensitivity right-hand
   side function was not provided.
SensDQparam - Cut-off parameter for the DQ approx. of the sensi. RHS [ scalar | 0.0 ]
   Specifies the value which controls the selection of the difference-quotient
   scheme used in evaluating the sensitivity right-hand sides (switch between
   simultaneous or separate evaluations of the two components in the sensitivity
   right-hand side). The default value 0.0 indicates the use of simultaenous approximation
   exclusively (centered or forward, depending on the value of SensDQtype.
   For SensDQparam &gt;= 1, CVODES uses a simultaneous approximation if the estimated
   DQ perturbations for states and parameters are within a factor of SensDQparam,
   and separate approximations otherwise. Note that a value SensDQparam &lt; 1
   will inhibit switching! This property is used only if a user-defined sensitivity
   right-hand side function was not provided.

        CVodeSensMalloc, CVSensRhsFn
```

CVodeMalloc

PURPOSE

CVodeMalloc allocates and initializes memory for CVODES.

SYNOPSIS

```
function [] = CVodeMalloc(fct,t0,y0,varargin)
```

DESCRIPTION

CVodeMalloc allocates and initializes memory for CVODES.

```
Usage: CVodeMalloc ( ODEFUN, T0, Y0 [, OPTIONS [, DATA] ] )

ODEFUN   is a function defining the ODE right-hand side: y' = f(t,y).
         This function must return a vector containing the current
         value of the righ-hand side.
T0       is the initial value of t.
Y0       is the initial condition vector y(t0).
OPTIONS  is an (optional) set of integration options, created with
         the CVodeSetOptions function.
DATA     is (optional) problem data passed unmodified to all
         user-provided functions when they are called. For example,
         YD = ODEFUN(T,Y,DATA).

See also: CVRhsFn
```

CVodeSensMalloc

PURPOSE

CVodeSensMalloc allocates and initializes memory for FSA with CVODES.

SYNOPSIS

```
function [] = CVodeSensMalloc(Ns,meth,yS0,varargin)
```

DESCRIPTION

CVodeSensMalloc allocates and initializes memory for FSA with CVODES.

```
Usage: CVodeSensMalloc ( NS, METH, YS0 [, OPTIONS ] )

NS       is the number of parameters with respect to which sensitivities
         are desired
METHOD   FSA solution method [ 'Simultaneous' | 'Staggered' ]
         Specifies the FSA method for treating the nonlinear system solution for
         sensitivity variables. In the simultaneous case, the nonlinear systems
         for states and all sensitivities are solved simultaneously. In the
         Staggered case, the nonlinear system for states is solved first and then
         the nonlinear systems for all sensitivities are solved at the same time.
YS0      Initial conditions for sensitivity variables.
         YS0 must be a matrix with N rows and Ns columns, where N is the problem
         dimension and Ns the number of sensitivity systems.
OPTIONS  is an (optional) set of FSA options, created with
         the CVodeSetFSAOptions function.
```

CVadjMalloc

PURPOSE

CVadjMalloc allocates and initializes memory for ASA with CVODES.

SYNOPSIS

```
function [] = CVadjMalloc(steps, interp)
```

DESCRIPTION

CVadjMalloc allocates and initializes memory for ASA with CVODES.

```
Usage: CVadjMalloc(STEPS, INTEPR)

STEPS    specifies the (maximum) number of integration steps between two
         consecutive check points.
INTERP   Specifies the type of interpolation used for estimating the forward
         solution during the backward integration phase. INTERP should be
         'Hermite', indicating cubic Hermite interpolation, or 'Polynomial',
         indicating variable order polynomial interpolation.
```

CVodeMallocB

PURPOSE

CVodeMallocB allocates and initializes backward memory for CVODES.

SYNOPSIS

```
function [] = CVodeMallocB(fctB,tB0,yB0,varargin)
```

DESCRIPTION

CVodeMallocB allocates and initializes backward memory for CVODES.

```
Usage:   CVodeMallocB ( FCTB, TB0, YB0 [, OPTIONSB] )

FCTB     is a function defining the adjoint ODE right-hand side.
         This function must return a vector containing the current
         value of the adjoint ODE righ-hand side.
TB0      is the final value of t.
YB0      is the final condition vector yB(tB0).
OPTIONSB is an (optional) set of integration options, created with
         the CVodeSetOptions function.

See also: CVRhsFn
```

CVode

PURPOSE

CVode integrates the ODE.

SYNOPSIS

```
function [status,t,y,varargout] = CVode(tout,itask)
```

DESCRIPTION

```
CVode integrates the ODE.

   Usage: [STATUS, T, Y] = CVode ( TOUT, ITASK )
          [STATUS, T, Y, YS] = CVode ( TOUT, ITASK )
          [STATUS, T, Y, YQ] = CVode  (TOUT, ITASK )
          [STATUS, T, Y, YQ, YS] = CVode ( TOUT, ITASK )

   If ITASK is 'Normal', then the solver integrates from its current internal
   T value to a point at or beyond TOUT, then interpolates to T = TOUT and returns
   Y(TOUT). If ITASK is 'OneStep', then the solver takes one internal time step
   and returns in Y the solution at the new internal time. In this case, TOUT
   is used only during the first call to CVode to determine the direction of
   integration and the rough scale of the problem. In either case, the time
   reached by the solver is returned in T. The 'NormalTstop' and 'OneStepTstop'
   modes are similar to 'Normal' and 'OneStep', respectively, except that the
   integration never proceeds past the value tstop.

   If quadratures were computed (see CVodeSetOptions), CVode will return their
   values at T in the vector YQ.

   If sensitivity calculations were enabled (see CVodeSetOptions), CVode will
   return their values at T in the matrix YS.

   On return, STATUS is one of the following:
     0: CVode succeeded and no roots were found.
     1: CVode succeded and returned at tstop.
     2: CVode succeeded, and found one or more roots.
    -1: Illegal attempt to call before CVodeMalloc
    -2: One of the inputs to CVode is illegal. This includes the situation
        when a component of the error weight vectors becomes &lt; 0 during internal
        time-stepping.
    -4: The solver took mxstep internal steps but could not reach TOUT. The
        default value for mxstep is 500.
    -5: The solver could not satisfy the accuracy demanded by the user for some
        internal step.
    -6: Error test failures occurred too many times (MXNEF = 7) during one internal
        time step
        or occurred with |h| = hmin.
    -7: Convergence test failures occurred too many times (MXNCF = 10) during one
        internal time step or occurred with |h| = hmin.
    -9: The linear solver's setup routine failed in an unrecoverable manner.
   -10: The linear solver's solve routine failed in an unrecoverable manner.

```

CVodeB

PURPOSE

CVodeB integrates the backward ODE.

SYNOPSIS

```
function [status,t,yB,varargout] = CVodeB(tout,itask)
```

DESCRIPTION

CVodeB integrates the backward ODE.

```
Usage:  [STATUS, T, YB] = CVodeB ( TOUT, ITASK )
        [STATUS, T, YB, YQB] = CVodeB ( TOUT, ITASK )

If ITASK is 'Normal', then the solver integrates from its current internal
T value to a point at or beyond TOUT, then interpolates to T = TOUT and returns
YB(TOUT). If ITASK is 'OneStep', then the solver takes one internal time step
and returns in YB the solution at the new internal time. In this case, TOUT
is used only during the first call to CVodeB to determine the direction of
integration and the rough scale of the problem. In either case, the time
reached by the solver is returned in T.

If quadratures were computed (see CVodeSetOptions), CVodeB will return their
values at T in the vector YQB.

On return, STATUS is one of the following:
  0: CVodeB succeeded and no roots were found.
 -2: One of the inputs to CVodeB is illegal.
 -4: The solver took mxstep internal steps but could not reach TOUT.
     The default value for mxstep is 500.
 -5: The solver could not satisfy the accuracy demanded by the user for
     some internal step.
 -6: Error test failures occurred too many times (MXNEF = 7) during one
     internal time step or occurred with |h| = hmin.
 -7: Convergence test failures occurred too many times (MXNCF = 10) during
     one internal time step or occurred with |h| = hmin.
 -9: The linear solver's setup routine failed in an unrecoverable manner.
-10: The linear solver's solve routine failed in an unrecoverable manner.
-101: Illegal attempt to call before initializing adjoint sensitivity
     (see CVodeMalloc).
-104: Illegal attempt to call before CVodeMallocB.
-108: Wrong value for TOUT.

```

CVodeGetStats

PURPOSE

CVodeGetStats returns run statistics for the CVODES solver.

SYNOPSIS

```
function si = CVodeGetStats()
```

DESCRIPTION

```
CVodeGetStats returns run statistics for the CVODES solver.

   Usage: STATS = CVodeGetStats

Fields in the structure STATS

o nst      - number of integration steps
o nfe      - number of right-hand side function evaluations
o nsetups  - number of linear solver setup calls
o netf     - number of error test failures
o nni      - number of nonlinear solver iterations
o ncfn     - number of convergence test failures
o qlast    - last method order used
o qcur     - current method order
o h0used   - actual initial step size used
o hlast    - last step size used
o hcur     - current step size
o tcur     - current time reached by the integrator
o RootInfo - strucutre with rootfinding information
o QuadInfo - structure with quadrature integration statistics
o LSInfo   - structure with linear solver statistics
o FSAInfo  - structure with forward sensitivity solver statistics

If rootfinding was requested, the structure RootInfo has the following fields

o nge   - number of calls to the rootfinding function
o roots - array of integers (a value of 1 in the i-th component means that the
          i-th rootfinding function has a root (upon a return with status=2 from
          CVode).

If quadratures were present, the structure QuadInfo has the following fields

o nfQe  - number of quadrature integrand function evaluations
o netfQ - number of error test failures for quadrature variables

The structure LSinfo has different fields, depending on the linear solver used.

  Fields in LSinfo for the 'Dense' linear solver

o name - 'Dense'
o njeD - number of Jacobian evaluations
o nfeD - number of right-hand side function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'Diag' linear solver

o name  - 'Diag'
o nfeDI - number of right-hand side function evaluations for difference-quotient
          Jacobian approximation

  Fields in LSinfo for the 'Band' linear solver

o name - 'Band'
o njeB - number of Jacobian evaluations
```

```
o nfeB - number of right-hand side function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'GMRES' and 'BiCGStab' linear solvers

o name  - 'GMRES' or 'BiCGStab'
o nli   - number of linear solver iterations
o npe   - number of preconditioner setups
o nps   - number of preconditioner solve function calls
o ncfl  - number of linear system convergence test failures
o njeSG - number of Jacobian-vector product evaluations
o nfeSG - number of right-hand side function evaluations for difference-quotient
          Jacobian-vector product approximation

If forward sensitivities were computed, the structure FSAInfo has the
following fields

o nfSe      - number of sensitivity right-hand side evaluations
o nfeS      - number of right-hand side evaluations for difference-quotient
              sensitivity right-hand side approximation
o nsetupsS  - number of linear solver setups triggered by sensitivity variables
o netfS     - number of error test failures for sensitivity variables
o nniS      - number of nonlinear solver iterations for sensitivity variables
o ncfnS     - number of convergence test failures due to sensitivity variables
```

CVodeGetStatsB

Purpose

CVodeGetStatsB returns run statistics for the backward CVODES solver.

Synopsis

```
function si = CVodeGetStatsB()
```

Description

CVodeGetStatsB returns run statistics for the backward CVODES solver.

```
   Usage: STATS = CVodeGetStatsB

Fields in the structure STATS

o nst - number of integration steps
o nfe - number of right-hand side function evaluations
o nsetups - number of linear solver setup calls
o netf - number of error test failures
o nni - number of nonlinear solver iterations
o ncfn - number of convergence test failures
o qlast - last method order used
o qcur - current method order
o h0used - actual initial step size used
o hlast - last step size used
o hcur - current step size
```

```
o tcur - current time reached by the integrator
o QuadInfo - structure with quadrature integration statistics
o LSInfo - structure with linear solver statistics

The structure LSinfo has different fields, depending on the linear solver used.

If quadratures were present, the structure QuadInfo has the following fields

o nfQe - number of quadrature integrand function evaluations
o netfQ - number of error test failures for quadrature variables

  Fields in LSinfo for the 'Dense' linear solver

o name - 'Dense'
o njeD - number of Jacobian evaluations
o nfeD - number of right-hand side function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'Diag' linear solver

o name - 'Diag'
o nfeDI - number of right-hand side function evaluations for difference-quotient
          Jacobian approximation

  Fields in LSinfo for the 'Band' linear solver

o name - 'Band'
o njeB - number of Jacobian evaluations
o nfeB - number of right-hand side function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'GMRES' and 'BiCGStab' linear solvers

o name - 'GMRES' or 'BiCGStab'
o nli - number of linear solver iterations
o npe - number of preconditioner setups
o nps - number of preconditioner solve function calls
o ncfl - number of linear system convergence test failures
o njeSG - number of Jacobian-vector product evaluations
o nfeSG -  number of right-hand side function evaluations for difference-quotient
          Jacobian-vector product approximation
```

CVodeGet

Purpose

CVodeGet extracts data from the CVODES solver memory.

Synopsis

```
function varargout = CVodeGet(key, varargin)
```

Description

CVodeGet extracts data from the CVODES solver memory.

```
Usage: RET = CVodeGet ( KEY [, P1 [, P2] ... ])

CVodeGet returns internal CVODES information based on KEY. For some values
of KEY, additional arguments may be required and/or more than one output is
returned.

KEY is a string and should be one of:
 o DerivSolution - Returns a vector containing the K-th order derivative
    of the solution at time T. The time T and order K must be passed through
    the input arguments P1 and P2, respectively:
    DKY = CVodeGet('DerivSolution', T, K)
 o ErrorWeights - Returns a vector containing the current error weights.
    EWT = CVodeGet('ErrorWeights')
 o CheckPointsInfo - Returns an array of structures with check point information.
    CK = CVodeGet('CheckPointInfo)
 o CurrentCheckPoint - Returns the address of the active check point
    ADDR = CVodeGet('CurrentCheckPoint');
 o DataPointInfo - Returns information stored for interpolation at the I-th data
    point in between the current check points. The index I must be passed through
    the agument P1.
    If the interpolation type was Hermite (see CVodeSetOptions), it returns two
    vectors, Y and YD:
    [Y, YD] = CVodeGet('DataPointInfo', I)
```

CVodeFree

Purpose

CVodeFree deallocates memory for the CVODES solver.

Synopsis

```
function [] = CVodeFree()
```

Description

CVodeFree deallocates memory for the CVODES solver.

```
Usage:  CVodeFree
```

CVodeMonitor

Purpose

CVodeMonitor is the default CVODES monitoring function.

Synopsis

```
function [new_data] = CVodeMonitor(call, T, Y, YQ, YS, data)
```

Description

```
CVodeMonitor is the default CVODES monitoring function.
   To use it, set the Monitor property in CVodeSetOptions to
   'CVodeMonitor' or to @CVodeMonitor and 'MonitorData' to mondata
   (defined as a structure).

   With default settings, this function plots the evolution of the step
   size, method order, and various counters.

   Various properties can be changed from their default values by passing
   to CVodeSetOptions, through the property 'MonitorData', a structure
   MONDATA with any of the following fields. If a field is not defined,
   the corresponding default value is used.

   Fields in MONDATA structure:
     o stats [ true | false ]
         If true, report the evolution of the step size and method order.
     o cntr [ true | false ]
         If true, report the evolution of the following counters:
         nst, nfe, nni, netf, ncfn (see CVodeGetStats)
     o mode [ 'graphical' | 'text' | 'both' ]
         In graphical mode, plot the evolutions of the above quantities.
         In text mode, print a table.
     o sol  [ true | false ]
         If true, plot solution components.
     o sensi [ true | false ]
         If true and if FSA is enabled, plot sensitivity components.
     o select [ array of integers ]
         To plot only particular solution components, specify their indeces in
         the field select. If not defined, but sol=true, all components are plotted.
     o updt [ integer | 50 ]
         Update frequency. Data is posted in blocks of dimension n.
     o skip [ integer | 0 ]
         Number of integrations steps to skip in collecting data to post.
     o dir [ 1 | -1 ]
         Specifies forward or backward integration.
     o post [ true | false ]
         If false, disable all posting. This option is necessary to disable
         monitoring on some processors when running in parallel.

   See also CVodeSetOptions, CVMonitorFn

   NOTES:
     1. The argument mondata is REQUIRED. Even if only the default options
        are desired, set mondata=struct; and pass it to CVodeSetOptions.
     2. The yQ argument is currently ignored.

2.2 Function types

CVBandJacFn

PURPOSE

CVBandJacFn - type for user provided banded Jacobian function.

SYNOPSIS

This is a script file.

DESCRIPTION

CVBandJacFn - type for user provided banded Jacobian function.

IVP Problem

```
   The function BJACFUN must be defined as
        FUNCTION [J, FLAG] = BJACFUN(T, Y, FY)
   and must return a matrix J corresponding to the banded Jacobian of f(t,y).
   The input argument FY contains the current value of f(t,y).
   If a user data structure DATA was specified in CVodeMalloc, then
   BJACFUN must be defined as
        FUNCTION [J, FLAG, NEW_DATA] = BJACFUN(T, Y, FY, DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix J,
   the BJACFUN function must also set NEW_DATA. Otherwise, it should
   set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function BJACFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.
```

Adjoint Problem

```
   The function BJACFUNB must be defined either as
        FUNCTION [JB, FLAG] = BJACFUNB(T, Y, YB, FYB)
   or as
        FUNCTION [JB, FLAG, NEW_DATA] = BJACFUNB(T, Y, YB, FYB, DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc. In either case, it must return the matrix JB, the
   Jacobian of fB(t,y,yB), with respect to yB. The input argument
   FYB contains the current value of f(t,y,yB).

   The function BJACFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also CVodeSetOptions

   See the CVODES user guide for more informaiton on the structure of
```

```
   a banded Jacobian.

   NOTE: BJACFUN and BJACFUNB are specified through the property
   JacobianFn to CVodeSetOptions and are used only if the property
   LinearSolver was set to 'Band'.
```

CVDenseJacFn

Purpose

```
CVDenseJacFn - type for user provided dense Jacobian function.
```

Synopsis

```
This is a script file.
```

Description

```
CVDenseJacFn - type for user provided dense Jacobian function.

IVP Problem

   The function DJACFUN must be defined as
        FUNCTION [J, FLAG] = DJACFUN(T, Y, FY)
   and must return a matrix J corresponding to the Jacobian of f(t,y).
   The input argument FY contains the current value of f(t,y).
   If a user data structure DATA was specified in CVodeMalloc, then
   DJACFUN must be defined as
        FUNCTION [J, FLAG, NEW_DATA] = DJACFUN(T, Y, FY, DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix J,
   the DJACFUN function must also set NEW_DATA. Otherwise, it should
   set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function DJACFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function DJACFUNB must be defined either as
        FUNCTION [JB, FLAG] = DJACFUNB(T, Y, YB, FYB)
   or as
        FUNCTION [JB, FLAG, NEW_DATA] = DJACFUNB(T, Y, YB, FYB, DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc. In either case, it must return the matrix JB, the
   Jacobian of fB(t,y,yB), with respect to yB. The input argument
   FYB contains the current value of f(t,y,yB).

   The function DJACFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.
```

```
   See also CVodeSetOptions

   NOTE: DJACFUN and DJACFUNB are specified through the property
   JacobianFn to CVodeSetOptions and are used only if the property
   LinearSolver was set to 'Dense'.
```

CVGcommFn

Purpose

```
CVGcommFn - type for user provided communication function (BBDPre).
```

Synopsis

```
This is a script file.
```

Description

```
CVGcommFn - type for user provided communication function (BBDPre).

IVP Problem

   The function GCOMFUN must be defined as
        FUNCTION FLAG = GCOMFUN(T, Y)
   and can be used to perform all interprocess communication necessary
   to evaluate the approximate right-hand side function for the BBDPre
   preconditioner module.
   If a user data structure DATA was specified in CVodeMalloc, then
   GCOMFUN must be defined as
        FUNCTION [FLAG, NEW_DATA] = GCOMFUN(T, Y, DATA)
   If the local modifications to the user data structure are needed
   in other user-provided functions then the GCOMFUN function must also
   set NEW_DATA. Otherwise, it should set NEW_DATA=[] (do not set
   NEW_DATA = DATA as it would lead to unnecessary copying).

   The function GCOMFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function GCOMFUNB must be defined either as
        FUNCTION FLAG = GCOMFUNB(T, Y, YB)
   or as
        FUNCTION [FLAG, NEW_DATA] = GCOMFUNB(T, Y, YB, DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc.

   The function GCOMFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also CVGlocalFn, CVodeSetOptions
```

```
NOTES:
  GCOMFUN and GCOMFUNB are specified through the GcommFn property in
  CVodeSetOptions and are used only if the property PrecModule is set
  to 'BBDPre'.

  Each call to GCOMFUN is preceded by a call to the RHS function
  ODEFUN with the same arguments T and Y (and YB in the case of GCOMFUNB).
  Thus GCOMFUN can omit any communication done by ODEFUN if relevant
  to the evaluation of G by GLOCFUN. If all necessary communication
  was done by ODEFUN, GCOMFUN need not be provided.
```

CVGlocalFn

Purpose

```
CVGlocalFn - type for user provided RHS approximation function (BBDPre).
```

Synopsis

```
This is a script file.
```

Description

```
CVGlocalFn - type for user provided RHS approximation function (BBDPre).

IVP Problem

   The function GLOCFUN must be defined as
        FUNCTION [GLOC, FLAG] = GLOCFUN(T,Y)
   and must return a vector GLOC corresponding to an approximation to f(t,y)
   which will be used in the BBDPRE preconditioner module. The case where
   G is mathematically identical to F is allowed.
   If a user data structure DATA was specified in CVodeMalloc, then
   GLOCFUN must be defined as
        FUNCTION [GLOC, FLAG, NEW_DATA] = GLOCFUN(T,Y,DATA)
   If the local modifications to the user data structure are needed
   in other user-provided functions then, besides setting the vector G,
   the GLOCFUN function must also set NEW_DATA. Otherwise, it should set
   NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function GLOCFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function GLOCFUNB must be defined either as
        FUNCTION [GLOCB, FLAG] = GLOCFUNB(T,Y,YB)
   or as
        FUNCTION [GLOCB, FLAG, NEW_DATA] = GLOCFUNB(T,Y,YB,DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc. In either case, it must return the vector GLOCB
   corresponding to an approximation to fB(t,y,yB).
```

```
   The function GLOCFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also CVGcommFn, CVodeSetOptions

   NOTE: GLOCFUN and GLOCFUNB are specified through the GlocalFn property
   in CVodeSetOptions and are used only if the property PrecModule
   is set to 'BBDPre'.
```

CVMonitorFn

Purpose

```
CVMonitorFn - type for user provided monitoring function.
```

Synopsis

```
This is a script file.
```

Description

```
CVMonitorFn - type for user provided monitoring function.

   The function MONFUN must be defined as
       FUNCTION [] = MONFUN(CALL, T, Y, YQ, YS)
   It is called after every internal CVode step and can be used to
   monitor the progress of the solver. MONFUN is called with CALL=0
   from CVodeMalloc at which time it should initialize itself and it
   is called with CALL=2 from CVodeFree. Otherwise, CALL=1.

   It receives as arguments the current time T, solution vector Y,
   and, if they were computed, quadrature vector YQ, and forward
   sensitivity matrix YS. If YQ and/or YS were not computed they
   are empty here.

   If additional data is needed inside MONFUN, it must be defined
   as
      FUNCTION NEW_MONDATA = MONFUN(CALL, T, Y, YQ, YS, MONDATA)
   If the local modifications to the user data structure need to be
   saved (e.g. for future calls to MONFUN), then MONFUN must set
   NEW_MONDATA. Otherwise, it should set NEW_MONDATA=[]
   (do not set NEW_MONDATA = DATA as it would lead to unnecessary copying).

   A sample monitoring function, CVodeMonitor, is provided with CVODES.

   See also CVodeSetOptions, CVodeMonitor

   NOTES:

   MONFUN is specified through the MonitorFn property in CVodeSetOptions.
   If this property is not set, or if it is empty, MONFUN is not used.
   MONDATA is specified through the MonitorData property in CVodeSetOptions.
```

If MONFUN is used on the backward integration phase, YS will always be empty.

See CVodeMonitor for an example of using MONDATA to write a single monitoring function that works both for the forward and backward integration phases.

CVQuadRhsFn

Purpose

CVQuadRhsFn - type for user provided quadrature RHS function.

Synopsis

This is a script file.

Description

CVQuadRhsFn - type for user provided quadrature RHS function.

IVP Problem

The function ODEQFUN must be defined as
```
     FUNCTION [YQD, FLAG] = ODEQFUN(T,Y)
```
and must return a vector YQD corresponding to fQ(t,y), the integrand for the integral to be evaluated.
If a user data structure DATA was specified in CVodeMalloc, then ODEQFUN must be defined as
```
     FUNCTION [YQD, FLAG, NEW_DATA] = ODEQFUN(T,Y,DATA)
```
If the local modifications to the user data structure are needed in other user-provided functions then, besides setting the vector YQD, the ODEQFUN function must also set NEW_DATA. Otherwise, it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to unnecessary copying).

The function ODEQFUN must set FLAG=0 if successful, FLAG<0 if an unrecoverable failure occurred, or FLAG>0 if a recoverable error occurred.

Adjoint Problem

The function ODEQFUNB must be defined either as
```
     FUNCTION [YQBD, FLAG] = ODEQFUNB(T,Y,YB)
```
or as
```
     FUNCTION [YQBD, FLAG, NEW_DATA] = ODEQFUNB(T,Y,YB,DATA)
```
depending on whether a user data structure DATA was specified in CVodeMalloc. In either case, it must return the vector YQBD corresponding to fQB(t,y,yB), the integrand for the integral to be evaluated on the backward phase.

The function ODEQFUNB must set FLAG=0 if successful, FLAG<0 if an unrecoverable failure occurred, or FLAG>0 if a recoverable error

occurred.

See also CVodeSetOptions

NOTE: ODEQFUN and ODEQFUNB are specified through the property
QuadRhsFn to CVodeSetOptions and are used only if the property
Quadratures was set to 'on'.

CVRhsFn

Purpose

CVRhsFn - type for user provided RHS type

Synopsis

This is a script file.

Description

CVRhsFn - type for user provided RHS type

IVP Problem

The function ODEFUN must be defined as
     FUNCTION [YD, FLAG] = ODEFUN(T,Y)
and must return a vector YD corresponding to f(t,y).
If a user data structure DATA was specified in CVodeMalloc, then
ODEFUN must be defined as
     FUNCTION [YD, FLAG, NEW_DATA] = ODEFUN(T,Y,DATA)
If the local modifications to the user data structure are needed
in other user-provided functions then, besides setting the vector YD,
the ODEFUN function must also set NEW_DATA. Otherwise, it should set
NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
unnecessary copying).

The function ODEFUN must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

Adjoint Problem

The function ODEFUNB must be defined either as
     FUNCTION [YBD, FLAG] = ODEFUNB(T,Y,YB)
or as
     FUNCTION [YBD, FLAG, NEW_DATA] = ODEFUNB(T,Y,YB,DATA)
depending on whether a user data structure DATA was specified in
CVodeMalloc. In either case, it must return the vector YBD
corresponding to fB(t,y,yB).

The function ODEFUNB must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

```
   See also CVodeMalloc, CVodeMallocB

   NOTE: ODEFUN and ODEFUNB are specified through the CVodeMalloc and
   CVodeMallocB functions, respectively.
```

CVRootFn

Purpose

```
CVRootFn - type for user provided root-finding function.
```

Synopsis

```
This is a script file.
```

Description

```
CVRootFn - type for user provided root-finding function.

   The function ROOTFUN must be defined as
        FUNCTION [G, FLAG] = ROOTFUN(T,Y)
   and must return a vector G corresponding to g(t,y).
   If a user data structure DATA was specified in CVodeMalloc, then
   ROOTFUN must be defined as
        FUNCTION [G, FLAG, NEW_DATA] = ROOTFUN(T,Y,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the vector G,
   the ROOTFUN function must also set NEW_DATA. Otherwise, it should
   set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function ROOTFUN must set FLAG=0 if successful, or FLAG~=0 if
   a failure occurred.

   See also CVodeSetOptions

   NOTE: ROOTFUN is specified through the RootsFn property in
   CVodeSetOptions and is used only if the property NumRoots is a
   positive integer.
```

CVSensRhsFn

Purpose

```
CVSensRhsFn - type for user provided sensitivity RHS function.
```

Synopsis

```
This is a script file.
```

Description

CVSensRhsFn - type for user provided sensitivity RHS function.

```
   The function ODESFUN must be defined as
        FUNCTION [YSD, FLAG] = ODESFUN(T,Y,YD,YS)
   and must return a matrix YSD corresponding to fS(t,y,yS).
   If a user data structure DATA was specified in CVodeMalloc, then
   ODESFUN must be defined as
        FUNCTION [YSD, FLAG, NEW_DATA] = ODESFUN(T,Y,YD,YS,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix YSD,
   the ODESFUN function must also set NEW_DATA. Otherwise, it should
   set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function ODESFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also CVodeSetFSAOptions

   NOTE: ODESFUN is specified through the property FSARhsFn to
         CVodeSetFSAOptions.
```

CVJacTimesVecFn

Purpose

CVJacTimesVecFn - type for user provided Jacobian times vector function.

Synopsis

This is a script file.

Description

CVJacTimesVecFn - type for user provided Jacobian times vector function.

IVP Problem

```
   The function JTVFUN must be defined as
        FUNCTION [JV, FLAG] = JTVFUN(T,Y,FY,V)
   and must return a vector JV corresponding to the product of the
   Jacobian of f(t,y) with the vector v.
   The input argument FY contains the current value of f(t,y).
   If a user data structure DATA was specified in CVodeMalloc, then
   JTVFUN must be defined as
        FUNCTION [JV, FLAG, NEW_DATA] = JTVFUN(T,Y,FY,V,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the vector JV,
   the JTVFUN function must also set NEW_DATA. Otherwise, it should set
   NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function JTVFUN must set FLAG=0 if successful, or FLAG~=0 if
```

```
   a failure occurred.

Adjoint Problem

   The function JTVFUNB must be defined either as
        FUNCTION [JVB, FLAG] = JTVFUNB(T,Y,YB,FYB,VB)
   or as
        FUNCTION [JVB, FLAG, NEW_DATA] = JTVFUNB(T,Y,YB,FYB,VB,DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc. In either case, it must return the vector JVB, the
   product of the Jacobian of fB(t,y,yB) with respect to yB and a vector
   vB. The input argument FYB contains the current value of f(t,y,yB).

   The function JTVFUNB must set FLAG=0 if successful, or FLAG~=0 if
   a failure occurred.

   See also CVodeSetOptions

   NOTE: JTVFUN and JTVFUNB are specified through the property
   JacobianFn to CVodeSetOptions and are used only if the property
   LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR'.
```

CVPrecSetupFn

Purpose

```
CVPrecSetupFn - type for user provided preconditioner setup function.
```

Synopsis

```
This is a script file.
```

Description

```
CVPrecSetupFn - type for user provided preconditioner setup function.

   The user-supplied preconditioner setup function PSETFUN and
   the user-supplied preconditioner solve function PSOLFUN
   together must define left and right preconditoner matrices
   P1 and P2 (either of which may be trivial), such that the
   product P1*P2 is an approximation to the Newton matrix
   M = I - gamma*J.  Here J is the system Jacobian J = df/dy,
   and gamma is a scalar proportional to the integration step
   size h.  The solution of systems P z = r, with P = P1 or P2,
   is to be carried out by the PrecSolve function, and PSETFUN
   is to do any necessary setup operations.

   The user-supplied preconditioner setup function PSETFUN
   is to evaluate and preprocess any Jacobian-related data
   needed by the preconditioner solve function PSOLFUN.
   This might include forming a crude approximate Jacobian,
   and performing an LU factorization on the resulting
   approximation to M.  This function will not be called in
   advance of every call to PSOLFUN, but instead will be called
```

```
   only as often as necessary to achieve convergence within the
   Newton iteration.  If the PSOLFUN function needs no
   preparation, the PSETFUN function need not be provided.

   For greater efficiency, the PSETFUN function may save
   Jacobian-related data and reuse it, rather than generating it
   from scratch.  In this case, it should use the input flag JOK
   to decide whether to recompute the data, and set the output
   flag JCUR accordingly.

   Each call to the PSETFUN function is preceded by a call to
   ODEFUN with the same (t,y) arguments.  Thus the PSETFUN
   function can use any auxiliary data that is computed and
   saved by the ODEFUN function and made accessible to PSETFUN.

IVP Problem

   The function PSETFUN must be defined as
        FUNCTION [JCUR, FLAG] = PSETFUN(T,Y,FY,JOK,GAMMA)
   and must return a logical flag JCUR (true if Jacobian information
   was recomputed and false if saved data was reused). If PSETFUN
   was successful, it must return FLAG=0. For a recoverable error (in
   which case the setup will be retried) it must set FLAG to a positive
   integer value. If an unrecoverable error occurs, it must set FLAG
   to a negative value, in which case the integration will be halted.
   The input argument FY contains the current value of f(t,y).
   If the input logical flag JOK is false, it means that
   Jacobian-related data must be recomputed from scratch. If it is true,
   it means that Jacobian data, if saved from the previous PSETFUN call
   can be reused (with the current value of GAMMA).

   If a user data structure DATA was specified in CVodeMalloc, then
   PSETFUN must be defined as
        FUNCTION [JCUR, FLAG, NEW_DATA] = PSETFUN(T,Y,FY,JOK,GAMMA,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the flags JCUR
   and FLAG, the PSETFUN function must also set NEW_DATA. Otherwise, it
   should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead
   to unnecessary copying).

Adjoint Problem

   The function PSETFUNB must be defined either as
        FUNCTION [JCURB, FLAG] = PSETFUNB(T,Y,YB,FYB,JOK,GAMMAB)
   or as
        FUNCTION [JCURB, FLAG, NEW_DATA] = PSETFUNB(T,Y,YB,FYB,JOK,GAMMAB,DATA)
   depending on whether a user data structure DATA was specified in
   CVodeMalloc. In either case, it must return the flags JCURB and FLAG.

   See also CVPrecSolveFn, CVodeSetOptions

   NOTE: PSETFUN and PSETFUNB are specified through the property
   PrecSetupFn to CVodeSetOptions and are used only if the property
   LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR' and if the
```

property PrecType is not 'None'.

CVPrecSolveFn

Purpose

CVPrecSolveFn - type for user provided preconditioner solve function.

Synopsis

This is a script file.

Description

CVPrecSolveFn - type for user provided preconditioner solve function.

The user-supplied preconditioner solve function PSOLFN
is to solve a linear system P z = r in which the matrix P is
one of the preconditioner matrices P1 or P2, depending on the
type of preconditioning chosen.

IVP Problem

The function PSOLFUN must be defined as
     FUNCTION [Z, FLAG] = PSOLFUN(T,Y,FY,R)
and must return a vector Z containing the solution of Pz=r.
If PSOLFUN was successful, it must return FLAG=0. For a recoverable
error (in which case the step will be retried) it must set FLAG to a
positive value. If an unrecoverable error occurs, it must set FLAG
to a negative value, in which case the integration will be halted.
The input argument FY contains the current value of f(t,y).

If a user data structure DATA was specified in CVodeMalloc, then
PSOLFUN must be defined as
     FUNCTION [Z, FLAG, NEW_DATA] = PSOLFUN(T,Y,FY,R,DATA)
If the local modifications to the user data structure are needed in
other user-provided functions then, besides setting the vector Z and
the flag FLAG, the PSOLFUN function must also set NEW_DATA. Otherwise,
it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would
lead to unnecessary copying).

Adjoint Problem

The function PSOLFUNB must be defined either as
     FUNCTION [ZB, FLAG] = PSOLFUNB(T,Y,YB,FYB,RB)
or as
     FUNCTION [ZB, FLAG, NEW_DATA] = PSOLFUNB(T,Y,YB,FYB,RB,DATA)
depending on whether a user data structure DATA was specified in
CVodeMalloc. In either case, it must return the vector ZB and the
flag FLAG.

See also CVPrecSetupFn, CVodeSetOptions

NOTE: PSOLFUN and PSOLFUNB are specified through the property

```
PrecSolveFn to CVodeSetOptions and are used only if the property
LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR' and if
the property PrecType is not 'None'.
```

3 MATLAB Interface to IDAS

The MATLAB interface to IDAS provides access to all functionality of the IDAS solver, including DAE simulation and sensitvity analysis (both forward and adjoint).

The interface consists of 9 user-callable functions. The user must provide several required and optional user-supplied functions which define the problem to be solved. The user-callable functions and the types of user-supplied functions are listed in Table 2 and fully documented later in this section. For more in depth details, consult also the IDAS user guide [4].

To illustrate the use of the IDAS MATLAB interface, several example problems are provided with SUNDIALSTB, both for serial and parallel computations. Most of them are MATLAB translations of example problems provided with IDAS.

Table 2: IDAS MATLAB interface functions

Functions	IDASetOptions	creates an options structure for IDAS.
	IDAMalloc	allocates and initializes memory for IDAS.
	IDASolve	integrates the ODE.
	IDAGetStats	returns statistics for the IDAS solver.
	IDAFree	deallocates memory for the IDAS solver.
	IDAMonitor	sample monitoring function.
Function types	IDAResFn	residual function
	IDARootFn	root-finding function
	IDADenseJacFn	dense Jacobian function
	IDABandJacFn	banded Jacobian function
	IDAJacTimesVecFn	Jacobian times vector function
	IDAPrecSetupFn	preconditioner setup function
	IDAPrecSolveFn	preconditioner solve function
	IDAGlocalFn	residual approximation function (BBDPre)
	IDAGcommFn	communication function (BBDPre)
	IDAMonitorFn	monitoring function

3.1 Interface functions

IDASetOptions

PURPOSE

```
IDASetOptions creates an options structure for IDAS.
```

SYNOPSIS

```
function options = IDASetOptions(varargin)
```

DESCRIPTION

```
IDASetOptions creates an options structure for IDAS.

   Usage: OPTIONS = IDASetOptions('NAME1',VALUE1,'NAME2',VALUE2,...)
          OPTIONS = IDASetOptions(OLDOPTIONS,'NAME1',VALUE1,...)
          OPTIONS = IDASetOptions(OLDOPTIONS,NEWOPTIONS)

   OPTIONS = IDASetOptions('NAME1',VALUE1,'NAME2',VALUE2,...) creates
   a IDAS options structure OPTIONS in which the named properties have
   the specified values. Any unspecified properties have default values.
   It is sufficient to type only the leading characters that uniquely
   identify the property. Case is ignored for property names.

   OPTIONS = IDASetOptions(OLDOPTIONS,'NAME1',VALUE1,...) alters an
   existing options structure OLDOPTIONS.

   OPTIONS = IDASetOptions(OLDOPTIONS,NEWOPTIONS) combines an existing
   options structure OLDOPTIONS with a new options structure NEWOPTIONS.
   Any new properties overwrite corresponding old properties.

   IDASetOptions with no input arguments displays all property names
   and their possible values.

IDASetOptions properties
(See also the IDAS User Guide)

RelTol - Relative tolerance [ positive scalar | 1e-4 ]
   RelTol defaults to 1e-4 and is applied to all components of the solution
   vector. See AbsTol.
AbsTol - Absolute tolerance [ positive scalar or vector | 1e-6 ]
   The relative and absolute tolerances define a vector of error weights
   with components
     ewt(i) = 1/(RelTol*|y(i)| + AbsTol)    if AbsTol is a scalar
     ewt(i) = 1/(RelTol*|y(i)| + AbsTol(i)) if AbsTol is a vector
   This vector is used in all error and convergence tests, which
   use a weighted RMS norm on all error-like vectors v:
     WRMSnorm(v) = sqrt( (1/N) sum(i=1..N) (v(i)*ewt(i))^2 ),
   where N is the problem dimension.
MaxNumSteps - Maximum number of steps [positive integer | 500]
   IDASolve will return with an error after taking MaxNumSteps internal steps
```

```
   in its attempt to reach the next output time.
InitialStep - Suggested initial stepsize [ positive scalar ]
   By default, IDASolve estimates an initial stepsize h0 at the initial time
   t0 as the solution of
     WRMSnorm(h0^2 ydd / 2) = 1
   where ydd is an estimated second derivative of y(t0).
MaxStep - Maximum stepsize [ positive scalar | inf ]
   Defines an upper bound on the integration step size.
MaxOrder - Maximum method order [ 1-5 for BDF | 5 ]
   Defines an upper bound on the linear multistep method order.
StopTime - Stopping time [ scalar ]
   Defines a value for the independent variable past which the solution
   is not to proceed.
RootsFn - Rootfinding function [ function ]
   To detect events (roots of functions), set this property to the event
   function. See IDARootFn.
NumRoots - Number of root functions [ integer | 0 ]
   Set NumRoots to the number of functions for which roots are monitored.
   If NumRoots is 0, rootfinding is disabled.

SuppressAlgVars - Suppres algebraic vars. from error test [ on | off ]
VariableTypes - Alg./diff. variables [ vector ]
ConstraintTypes - Simple bound constraints [ vector ]

LinearSolver - Linear solver type [Dense|Band|GMRES|BiCGStab|TFQMR]
   Specifies the type of linear solver to be used for the Newton nonlinear
   solver. Valid choices are: Dense (direct, dense Jacobian), Band (direct,
   banded Jacobian), GMRES (iterative, scaled preconditioned GMRES),
   BiCGStab (iterative, scaled preconditioned stabilized BiCG), TFQMR
   (iterative, scaled transpose-free QMR).
   The GMRES, BiCGStab, and TFQMR are matrix-free linear solvers.
JacobianFn - Jacobian function [ function ]
   This propeerty is overloaded. Set this value to a function that returns
   Jacobian information consistent with the linear solver used (see Linsolver).
   If not specified, IDAS uses difference quotient approximations.
   For the Dense linear solver, JacobianFn must be of type IDADenseJacFn and
   must return a dense Jacobian matrix. For the Band linear solver, JacobianFn
   must be of type IDABandJacFn and must return a banded Jacobian matrix.
   For the iterative linear solvers, GMRES, BiCGStab, and TFQMR, JacobianFn must
   be of type IDAJacTimesVecFn and must return a Jacobian-vector product.
KrylovMaxDim - Maximum number of Krylov subspace vectors [ integer | 5 ]
   Specifies the maximum number of vectors in the Krylov subspace. This property
   is used only if an iterative linear solver, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver).
GramSchmidtType - Gram-Schmidt orthogonalization [ Classical | Modified ]
   Specifies the type of Gram-Schmidt orthogonalization (classical or modified).
   This property is used only if the GMRES linear solver is used (see LinSolver).
PrecModule - Preconditioner module [ BBDPre | UserDefined ]
   If PrecModule = 'UserDefined', then the user must provide at least a
   preconditioner solve function (see PrecSolveFn)
   IDAS provides one general-purpose preconditioner module, BBDPre, which can
   be only used with parallel vectors. It provide a preconditioner matrix that
   is block-diagonal with banded blocks. The blocking corresponds to the
   distribution of the dependent variable vector y among the processors.
```

```
   Each preconditioner block is generated from the Jacobian of the local part
   (on the current processor) of a given function g(t,y,yp) approximating
   f(t,y,yp) (see GlocalFn). The blocks are generated by a difference quotient
   scheme on each processor independently. This scheme utilizes an assumed
   banded structure with given half-bandwidths, mldq and mudq (specified through
   LowerBwidthDQ and UpperBwidthDQ, respectively). However, the banded Jacobian
   block kept by the scheme has half-bandwiths ml and mu (specified through
   LowerBwidth and UpperBwidth), which may be smaller.
PrecSetupFn - Preconditioner setup function [ function ]
   If PrecType is not 'None', PrecSetupFn specifies an optional function which,
   together with PrecSolve, defines the preconditioner matrix, which must be an
   aproximation to the Newton matrix. PrecSetupFn must be of type IDAPrecSetupFn.
PrecSolveFn - Preconditioner solve function [ function ]
   If PrecType is not 'None', PrecSolveFn specifies a required function which
   must solve a linear system Pz = r, for given r. PrecSolveFn must be of type
   IDAPrecSolveFn.
GlocalFn - Local residual approximation function for BBDPre [ function ]
   If PrecModule is BBDPre, GlocalFn specifies a required function that
   evaluates a local approximation to the DAE residual. GlocalFn must
   be of type IDAGlocFn.
GcommFn - Inter-process communication function for BBDPre [ function ]
   If PrecModule is BBDPre, GcommFn specifies an optional function
   to perform any inter-process communication required for the evaluation of
   GlocalFn. GcommFn must be of type IDAGcommFn.
LowerBwidth - Jacobian/preconditioner lower bandwidth [ integer | 0 ]
   This property is overloaded. If the Band linear solver is used (see LinSolver),
   it specifies the lower half-bandwidth of the band Jacobian approximation.
   If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver) and if the BBDPre preconditioner module in IDAS is used
   (see PrecModule), it specifies the lower half-bandwidth of the retained
   banded approximation of the local Jacobian block.
   LowerBwidth defaults to 0 (no sub-diagonals).
UpperBwidth - Jacobian/preconditioner upper bandwidth [ integer | 0 ]
   This property is overloaded. If the Band linear solver is used (see LinSolver),
   it specifies the upper half-bandwidth of the band Jacobian approximation.
   If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver) and if the BBDPre preconditioner module in IDAS is used
   (see PrecModule), it specifies the upper half-bandwidth of the retained
   banded approximation of the local Jacobian block.
   UpperBwidth defaults to 0 (no super-diagonals).
LowerBwidthDQ - BBDPre preconditioner DQ lower bandwidth [ integer | 0 ]
   Specifies the lower half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).
UpperBwidthDQ - BBDPre preconditioner DQ upper bandwidth [ integer | 0 ]
   Specifies the upper half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).

Quadratures - Quadrature integration [ on | off ]
   Enables or disables quadrature integration.
QuadRhsFn - Quadrature residual function [ function ]
   Specifies the user-supplied function to evaluate the integrand for
   quadrature computations. See IDAQuadRhsfn.
QuadInitCond - Initial conditions for quadrature variables [ vector ]
   Specifies the initial conditions for quadrature variables.
```

```
QuadErrControl - Error control strategy for quadrature variables [ on | off ]
   Specifies whether quadrature variables are included in the error test.
QuadRelTol - Relative tolerance for quadrature variables [ scalar 1e-4 ]
   Specifies the relative tolerance for quadrature variables. This parameter is
   used only if QuadErrCon=on.
QuadAbsTol - Absolute tolerance for quadrature variables [ scalar or vector 1e-6 ]
   Specifies the absolute tolerance for quadrature variables. This parameter is
   used only if QuadErrCon=on.

ASANumDataPoints - Number of data points for ASA [ integer | 100 ]
   Specifies the (maximum) number of integration steps between two consecutive
   check points.
ASAInterpType - Type of interpolation [ Polynomial | Hermite ]
   Specifies the type of interpolation used for estimating the forward solution
   during the backward integration phase. At this time, the only option is
   'Hermite', specifying cubic Hermite interpolation.

MonitorFn - User-provied monitoring function [ function ]
   Specifies a function that is called after each successful integration step.
   This function must have type IDAMonitorFn. A simple monitoring function,
   IDAMonitor is provided with IDAS.
MonitorData - User-provied data for the monitoring function [ struct ]
   Specifies a data structure that is passed to the Monitor function every time
   it is called.

IDAMalloc

Purpose

IDAMalloc allocates and initializes memory for IDAS.

Synopsis

```
function [] = IDAMalloc(fct,t0,yy0,yp0,varargin)
```

Description

IDAMalloc allocates and initializes memory for IDAS.

```
   Usage: IDAMalloc ( DAEFUN, T0, YY0, YP0 [, OPTIONS [, DATA] ] )

   DAEFUN   is a function defining the DAE residual: f(t,yy,yp).
            This function must return a vector containing the current
            value of the residual.
   T0       is the initial value of t.
   YY0      is the initial condition vector y(t0).
   YP0      is the initial condition vector y'(t0).
```

```
   OPTIONS  is an (optional) set of integration options, created with
            the IDASetOptions function.
   DATA     is (optional) problem data passed unmodified to all
            user-provided functions when they are called. For example,
            YD = DAEFUN(T,YY,YP,DATA).

  See also: IDARhsFn
```

IDASolve

Purpose

IDASolve integrates the DAE.

Synopsis

```
function [status, t, yy, yp, varargout] = IDASolve(tout,itask)
```

Description

IDASolve integrates the DAE.

```
   Usage: [STATUS, T, YY, YP] = IDASolve ( TOUT, ITASK )
          [STATUS, T, YY, YP, YQ] = IDASolve  (TOUT, ITASK )
          [STATUS, T, YY, YP, YYS, YPS] = IDASolve ( TOUT, ITASK )
          [STATUS, T, YY, YP, YQ, YYS, YPS] = IDASolve ( TOUT, ITASK )

   If ITASK is 'Normal', then the solver integrates from its current internal
   T value to a point at or beyond TOUT, then interpolates to T = TOUT and
   returns YY(TOUT) and YP(TOUT). If ITASK is 'OneStep', then the solver takes
   one internal time step and returns in YY and YP the solution at the new
   internal time. In this case, TOUT is used only during the first call to
   IDASolve to determine the direction of integration and the rough scale of
   the problem. In either case, the time reached by the solver is returned in T.
   The 'NormalTstop' and 'OneStepTstop' modes are similar to 'Normal' and
   'OneStep', respectively, except that the integration never proceeds past
   the value tstop.

   If quadratures were computed (see IDASetOptions), IDASolve will return their
   values at T in the vector YQ.

   If sensitivity calculations were enabled (see IDASetOptions), IDASolve will
   return their values at T in the matrix YS.

   On return, STATUS is one of the following:
     0: IDASolve succeeded and no roots were found.
     1: IDASolve succeded and returned at tstop.
     2: IDASolve succeeded, and found one or more roots.
    -1: Illegal attempt to call before IDAMalloc
    -2: One of the inputs to IDASolve is illegal. This includes the situation
        when a component of the error weight vectors becomes &lt; 0 during internal
        time-stepping.
    -4: The solver took mxstep internal steps but could not reach TOUT. The
        default value for mxstep is 500.
```

```
    -5: The solver could not satisfy the accuracy demanded by the user for some
        internal step.
    -6: Error test failures occurred too many times (MXNEF = 7) during one internal
        time step
        or occurred with |h| = hmin.
    -7: Convergence test failures occurred too many times (MXNCF = 10) during one
        internal time step or occurred with |h| = hmin.
    -9: The linear solver's setup routine failed in an unrecoverable manner.
   -10: The linear solver's solve routine failed in an unrecoverable manner.

```

IDAGetStats

Purpose

```
IDAGetStats returns run statistics for the IDAS solver.
```

Synopsis

```
function si = IDAGetStats()
```

Description

```
IDAGetStats returns run statistics for the IDAS solver.

   Usage: STATS = IDAGetStats

Fields in the structure STATS

o nst      - number of integration steps
o nre      - number of residual function evaluations
o nsetups  - number of linear solver setup calls
o netf     - number of error test failures
o nni      - number of nonlinear solver iterations
o ncfn     - number of convergence test failures
o qlast    - last method order used
o qcur     - current method order
o h0used   - actual initial step size used
o hlast    - last step size used
o hcur     - current step size
o tcur     - current time reached by the integrator
o RootInfo - strucutre with rootfinding information
o QuadInfo - structure with quadrature integration statistics
o LSInfo   - structure with linear solver statistics
o FSAInfo  - structure with forward sensitivity solver statistics

If rootfinding was requested, the structure RootInfo has the following fields

o nge   - number of calls to the rootfinding function
o roots - array of integers (a value of 1 in the i-th component means that the
          i-th rootfinding function has a root (upon a return with status=2 from
          IDASolve).
```

```
If quadratures were present, the structure QuadInfo has the following fields

o nfQe  - number of quadrature integrand function evaluations
o netfQ - number of error test failures for quadrature variables

The structure LSinfo has different fields, depending on the linear solver used.

  Fields in LSinfo for the 'Dense' linear solver

o name - 'Dense'
o njeD - number of Jacobian evaluations
o nreD - number of residual function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'Band' linear solver

o name - 'Band'
o njeB - number of Jacobian evaluations
o nreB - number of residual function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'GMRES' and 'BiCGStab' linear solvers

o name  - 'GMRES' or 'BiCGStab'
o nli   - number of linear solver iterations
o npe   - number of preconditioner setups
o nps   - number of preconditioner solve function calls
o ncfl  - number of linear system convergence test failures
o njeSG - number of Jacobian-vector product evaluations
o nreSG - number of residual function evaluations for difference-quotient
          Jacobian-vector product approximation

If forward sensitivities were computed, the structure FSAInfo has the
following fields

o nrSe      - number of sensitivity residual evaluations
o nreS      - number of residual evaluations for difference-quotient
              sensitivity residual approximation
o nsetupsS  - number of linear solver setups triggered by sensitivity variables
o netfS     - number of error test failures for sensitivity variables
o nniS      - number of nonlinear solver iterations for sensitivity variables
o ncfnS     - number of convergence test failures due to sensitivity variables
```

IDAFree

Purpose

IDAFree deallocates memory for the IDAS solver.

Synopsis

```
function [] = IDAFree()
```

Description

IDAFree deallocates memory for the IDAS solver.

Usage: IDAFree

IDAMonitor

Purpose

IDAMonitor is the default IDAS monitoring function.

Synopsis

```
function [new_data] = IDAMonitor(call, T, YY, YP, YQ, YYS, YPS, data)
```

Description

```
IDAMonitor is the default IDAS monitoring function.
   To use it, set the Monitor property in IDASetOptions to
   'IDAMonitor' or to @IDAMonitor and 'MonitorData' to mondata
   (defined as a structure).

   With default settings, this function plots the evolution of the step
   size, method order, and various counters.

   Various properties can be changed from their default values by passing
   to IDASetOptions, through the property 'MonitorData', a structure
   MONDATA with any of the following fields. If a field is not defined,
   the corresponding default value is used.

   Fields in MONDATA structure:
     o stats [ true | false ]
         If true, report the evolution of the step size and method order.
     o cntr [ true | false ]
         If true, report the evolution of the following counters:
         nst, nre, nni, netf, ncfn (see IDAGetStats)
     o mode [ 'graphical' | 'text' | 'both' ]
         In graphical mode, plot the evolutions of the above quantities.
         In text mode, print a table.
     o xaxis [ 'linear' | 'log' ]
         Type of the time axis for the stepsize, order, and counter plots
         (graphical mode only).
     o sol  [ true | false ]
         If true, plot solution components.
     o sensi [ true | false ]
         If true and if FSA is enabled, plot sensitivity components.
     o select [ array of integers ]
         To plot only particular solution components, specify their indeces in
         the field select. If not defined, but sol=true, all components are plotted.
     o updt [ integer | 50 ]
         Update frequency. Data is posted in blocks of dimension n.
     o skip [ integer | 0 ]
         Number of integrations steps to skip in collecting data to post.
     o dir [ 1 | -1 ]
         Specifies forward or backward integration.
```

```
    o post [ true | false ]
        If false, disable all posting. This option is necessary to disable
        monitoring on some processors when running in parallel.

  See also IDASetOptions, IDAMonitorFn

  NOTES:
    1. The argument mondata is REQUIRED. Even if only the default options
       are desired, set mondata=struct; and pass it to IDASetOptions.
    2. The arguments YP, YQ, and YPS are currently ignored.

3.2 Function types

IDABandJacFn

PURPOSE

IDABandJacFn - type for user provided banded Jacobian function.

SYNOPSIS

This is a script file.

DESCRIPTION

IDABandJacFn - type for user provided banded Jacobian function.

IVP Problem

The function BJACFUN must be defined as
FUNCTION [J, FLAG] = BJACFUN(T, YY, YP, RR, CJ)
and must return a matrix J corresponding to the banded Jacobian
(df/dyy + cj*df/dyp).
The input argument RR contains the current value of f(t,yy,yp).
If a user data structure DATA was specified in IDAMalloc, then
BJACFUN must be defined as
FUNCTION [J, FLAG, NEW_DATA] = BJACFUN(T, YY, YP, RR, CJ, DATA)
If the local modifications to the user data structure are needed in
other user-provided functions then, besides setting the matrix J,
the BJACFUN function must also set NEW_DATA. Otherwise, it should
set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
unnecessary copying).

The function BJACFUN must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

Adjoint Problem

The function BJACFUNB must be defined either as
FUNCTION [JB, FLAG] = BJACFUNB(T, YY, YP, YYB, YPB, RRB, CJB)
or as
FUNCTION [JB,FLAG,NEW_DATA] = BJACFUNB(T,YY,YP,YYB,YPB,RRB,CJB)
depending on whether a user data structure DATA was specified in
IDAMalloc. In either case, it must return the matrix JB, the
Jacobian (dfB/dyyB + cjB*dfB/dypB)of fB(t,y,yB). The input argument
RRB contains the current value of f(t,yy,yp,yyB,ypB).

The function BJACFUNB must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

See also IDASetOptions

```
   See the IDAS user guide for more informaiton on the structure of
   a banded Jacobian.

   NOTE: BJACFUN and BJACFUNB are specified through the property
   JacobianFn to IDASetOptions and are used only if the property
   LinearSolver was set to 'Band'.
```

IDADenseJacFn

Purpose

```
IDADenseJacFn - type for user provided dense Jacobian function.
```

Synopsis

```
This is a script file.
```

Description

```
IDADenseJacFn - type for user provided dense Jacobian function.

IVP Problem

   The function DJACFUN must be defined as
        FUNCTION [J, FLAG] = DJACFUN(T, YY, YP, RR, CJ)
   and must return a matrix J corresponding to the Jacobian
   (df/dyy + cj*df/dyp).
   The input argument RR contains the current value of f(t,yy,yp).
   If a user data structure DATA was specified in IDAMalloc, then
   DJACFUN must be defined as
        FUNCTION [J, FLAG, NEW_DATA] = DJACFUN(T, YY, YP, RR, CJ, DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix J,
   the DJACFUN function must also set NEW_DATA. Otherwise, it should
   set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function DJACFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function DJACFUNB must be defined either as
        FUNCTION [JB, FLAG] = DJACFUNB(T, YY, YP, YYB, YPB, RRB, CJB)
   or as
        FUNCTION [JB,FLAG,NEW_DATA] = DJACFUNB(T,YY,YP,YYB,YPB,RRB,CJB,DATA)
   depending on whether a user data structure DATA was specified in
   IDAMalloc. In either case, it must return the matrix JB, the
   Jacobian (dfB/dyyB + cjb*dfB/dypB). The input argument RRB contains
   the current value of f(t,yy,yp,yyB,ypB).

   The function DJACFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
```

occurred.

See also IDASetOptions

NOTE: DJACFUN and DJACFUNB are specified through the property JacobianFn to IDASetOptions and are used only if the property LinearSolver was set to 'Dense'.

IDAGcommFn

Purpose

IDAGcommFn - type for user provided communication function (BBDPre).

Synopsis

This is a script file.

Description

IDAGcommFn - type for user provided communication function (BBDPre).

IVP Problem

The function GCOMFUN must be defined as
```
     FUNCTION FLAG = GCOMFUN(T, YY, YP)
```
and can be used to perform all interprocess communication necessary to evaluate the approximate residual function for the BBDPre preconditioner module.
If a user data structure DATA was specified in IDAMalloc, then GCOMFUN must be defined as
```
     FUNCTION [FLAG, NEW_DATA] = GCOMFUN(T, YY, YP, DATA)
```
If the local modifications to the user data structure are needed in other user-provided functions then the GCOMFUN function must also set NEW_DATA. Otherwise, it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to unnecessary copying).

The function GCOMFUN must set FLAG=0 if successful, FLAG<0 if an unrecoverable failure occurred, or FLAG>0 if a recoverable error occurred.

Adjoint Problem

The function GCOMFUNB must be defined either as
```
     FUNCTION FLAG = GCOMFUNB(T, YY, YP, YYB, YPB)
```
or as
```
     FUNCTION [FLAG, NEW_DATA] = GCOMFUNB(T, YY, YP, YYB, YPB, DATA)
```
depending on whether a user data structure DATA was specified in IDAMalloc.

The function GCOMFUNB must set FLAG=0 if successful, FLAG<0 if an unrecoverable failure occurred, or FLAG>0 if a recoverable error occurred.

```
   See also IDAGlocalFn, IDASetOptions

   NOTES:
     GCOMFUN and GCOMFUNB are specified through the GcommFn property in
     IDASetOptions and are used only if the property PrecModule is set
     to 'BBDPre'.

     Each call to GCOMFUN is preceded by a call to the residual function
     DAEFUN with the same arguments T, YY, and YP (and YYB and YPB in the
     case of GCOMFUNB). Thus GCOMFUN can omit any communication done by
     DAEFUN if relevant to the evaluation of G by GLOCFUN.
     If all necessary communication was done by DAEFUN, GCOMFUN need
     not be provided.
```

IDAGlocalFn

Purpose

```
IDAGlocalFn - type for user provided RES approximation function (BBDPre).
```

Synopsis

```
This is a script file.
```

Description

```
IDAGlocalFn - type for user provided RES approximation function (BBDPre).

IVP Problem

   The function GLOCFUN must be defined as
        FUNCTION [GLOC, FLAG] = GLOCFUN(T,YY,YP)
   and must return a vector GLOC corresponding to an approximation to f(t,yy,yp)
   which will be used in the BBDPRE preconditioner module. The case where
   G is mathematically identical to F is allowed.
   If a user data structure DATA was specified in IDAMalloc, then
   GLOCFUN must be defined as
        FUNCTION [GLOC, FLAG, NEW_DATA] = GLOCFUN(T,YY,YP,DATA)
   If the local modifications to the user data structure are needed
   in other user-provided functions then, besides setting the vector G,
   the GLOCFUN function must also set NEW_DATA. Otherwise, it should set
   NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function GLOCFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function GLOCFUNB must be defined either as
        FUNCTION [GLOCB, FLAG] = GLOCFUNB(T,YY,YP,YYB,YPB)
   or as
        FUNCTION [GLOCB, FLAG, NEW_DATA] = GLOCFUNB(T,YY,YP,YYB,YPB,DATA)
```

depending on whether a user data structure DATA was specified in
IDAMalloc. In either case, it must return the vector GLOCB
corresponding to an approximation to fB(t,yy,yp,yyB,ypB).

The function GLOCFUNB must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

See also IDAGcommFn, IDASetOptions

NOTE: GLOCFUN and GLOCFUNB are specified through the GlocalFn property
in IDASetOptions and are used only if the property PrecModule
is set to 'BBDPre'.

IDAMonitorFn

Purpose

IDAMonitorFn - type for user provided monitoring function.

Synopsis

This is a script file.

Description

IDAMonitorFn - type for user provided monitoring function.

The function MONFUN must be defined as
    FUNCTION [] = MONFUN(CALL, T, YY, YP, YQ, YYS, YPS)
It is called after every internal IDASolve step and can be used to
monitor the progress of the solver. MONFUN is called with CALL=0
from IDAMalloc at which time it should initialize itself and it
is called with CALL=2 from IDAFree. Otherwise, CALL=1.

It receives as arguments the current time T, solution vectors
YY and YP, and, if they were computed, quadrature vector YQ, and
forward sensitivity matrices YYS and YPS If YQ and/or YYS, YPS were
not computed they are empty here.

If additional data is needed inside MONFUN, it must be defined
as
   FUNCTION NEW_MONDATA = MONFUN(CALL, T, YY, YP, YQ, YYS, YPS, MONDATA)
If the local modifications to the user data structure need to be
saved (e.g. for future calls to MONFUN), then MONFUN must set
NEW_MONDATA. Otherwise, it should set NEW_MONDATA=[]
(do not set NEW_MONDATA = DATA as it would lead to unnecessary copying).

A sample monitoring function, IDAMonitor, is provided with IDAS.

See also IDASetOptions, IDAMonitor

NOTES:

```
   MONFUN is specified through the MonitorFn property in IDASetOptions.
   If this property is not set, or if it is empty, MONFUN is not used.
   MONDATA is specified through the MonitorData property in IDASetOptions.

   If MONFUN is used on the backward integration phase, YYS and YPS will
   always be empty.

   See IDAMonitor for an example of using MONDATA to write a single
   monitoring function that works both for the forward and backward
   integration phases.
```

IDAResFn

Purpose

```
IDAResFn - type for user provided RHS type
```

Synopsis

```
This is a script file.
```

Description

```
IDAResFn - type for user provided RHS type

IVP Problem

   The function DAEFUN must be defined as
        FUNCTION [R, FLAG] = DAEFUN(T, YY, YP)
   and must return a vector R corresponding to f(t,yy,yp).
   If a user data structure DATA was specified in IDAMalloc, then
   DAEFUN must be defined as
        FUNCTION [R, FLAG, NEW_DATA] = DAEFUN(T, YY, YP, DATA)
   If the local modifications to the user data structure are needed
   in other user-provided functions then, besides setting the vector YD,
   the DAEFUN function must also set NEW_DATA. Otherwise, it should set
   NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function DAEFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

Adjoint Problem

   The function DAEFUNB must be defined either as
        FUNCTION [RB, FLAG] = DAEFUNB(T, YY, YP, YYB, YPB)
   or as
        FUNCTION [RB, FLAG, NEW_DATA] = DAEFUNB(T, YY, YP, YYB, YPB, DATA)
   depending on whether a user data structure DATA was specified in
   IDAMalloc. In either case, it must return the vector RB
   corresponding to fB(t,yy,yp,yyB,ypB).

   The function DAEFUNB must set FLAG=0 if successful, FLAG&lt;0 if an
```

unrecoverable failure occurred, or FLAG>0 if a recoverable error occurred.

See also IDAMalloc, IDAMallocB

NOTE: DAEFUN and DAEFUNB are specified through the IDAMalloc and IDAMallocB functions, respectively.

IDARootFn

Purpose

IDARootFn - type for user provided root-finding function.

Synopsis

This is a script file.

Description

IDARootFn - type for user provided root-finding function.

The function ROOTFUN must be defined as
```
     FUNCTION [G, FLAG] = ROOTFUN(T,YY,YP)
```
and must return a vector G corresponding to g(t,yy,yp).
If a user data structure DATA was specified in IDAMalloc, then ROOTFUN must be defined as
```
     FUNCTION [G, FLAG, NEW_DATA] = ROOTFUN(T,YY,YP,DATA)
```
If the local modifications to the user data structure are needed in other user-provided functions then, besides setting the vector G, the ROOTFUN function must also set NEW_DATA. Otherwise, it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to unnecessary copying).

The function ROOTFUN must set FLAG=0 if successful, or FLAG~=0 if a failure occurred.

See also IDASetOptions

NOTE: ROOTFUN is specified through the RootsFn property in IDASetOptions and is used only if the property NumRoots is a positive integer.

IDAJacTimesVecFn

Purpose

IDAJacTimesVecFn - type for user provided Jacobian times vector function.

Synopsis

This is a script file.

Description

```
IDAJacTimesVecFn - type for user provided Jacobian times vector function.

IVP Problem

   The function JTVFUN must be defined as
        FUNCTION [JV, FLAG] = JTVFUN(T,YY,YP,RR,V,CJ)
   and must return a vector JV corresponding to the product of the
   Jacobian ( df/dyy + cj * df/dyp ) with the vector v.
   The input argument RR contains the current value of f(t,yy,yp).
   If a user data structure DATA was specified in IDAMalloc, then
   JTVFUN must be defined as
        FUNCTION [JV, FLAG, NEW_DATA] = JTVFUN(T,YY,YP,RR,V,CJ,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the vector JV,
   the JTVFUN function must also set NEW_DATA. Otherwise, it should set
   NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   The function JTVFUN must set FLAG=0 if successful, or FLAG~=0 if
   a failure occurred.

Adjoint Problem

   The function JTVFUNB must be defined either as
        FUNCTION [JVB,FLAG] = JTVFUNB(T,YY,YP,YYB,YPB,RRB,VB,CJB)
   or as
        FUNCTION [JVB,FLAG,NEW_DATA] = JTVFUNB(T,YY,YP,YYB,YPB,RRB,VB,CJB,DATA)
   depending on whether a user data structure DATA was specified in
   IDAMalloc. In either case, it must return the vector JVB, the
   product of the Jacobian (dfB/dyyB + cj * dfB/dypB) and a vector
   vB. The input argument RRB contains the current value of f(t,yy,yp,yyB,ypB).

   The function JTVFUNB must set FLAG=0 if successful, or FLAG~=0 if
   a failure occurred.

   See also IDASetOptions

   NOTE: JTVFUN and JTVFUNB are specified through the property
   JacobianFn to IDASetOptions and are used only if the property
   LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR'.
```

IDAPrecSetupFn

Purpose

```
IDAPrecSetupFn - type for user provided preconditioner setup function.
```

Synopsis

```
This is a script file.
```

Description

```
IDAPrecSetupFn - type for user provided preconditioner setup function.

   The user-supplied preconditioner setup function PSETFUN and
   the user-supplied preconditioner solve function PSOLFUN
   together must define a preconditoner matrix P which is an
   approximation to the Newton matrix M = J_yy - cj*J_yp.
   Here J_yy = df/dyy, J_yp = df/dyp, and cj is a scalar proportional
   to the integration step size h.  The solution of systems P z = r,
   is to be carried out by the PrecSolve function, and PSETFUN
   is to do any necessary setup operations.

   The user-supplied preconditioner setup function PSETFUN
   is to evaluate and preprocess any Jacobian-related data
   needed by the preconditioner solve function PSOLFUN.
   This might include forming a crude approximate Jacobian,
   and performing an LU factorization on the resulting
   approximation to M.  This function will not be called in
   advance of every call to PSOLFUN, but instead will be called
   only as often as necessary to achieve convergence within the
   Newton iteration.  If the PSOLFUN function needs no
   preparation, the PSETFUN function need not be provided.

   For greater efficiency, the PSETFUN function may save
   Jacobian-related data and reuse it, rather than generating it
   from scratch.  In this case, it should use the input flag JOK
   to decide whether to recompute the data, and set the output
   flag JCUR accordingly.

   Each call to the PSETFUN function is preceded by a call to
   DAEFUN with the same (t,yy,yp) arguments.  Thus the PSETFUN
   function can use any auxiliary data that is computed and
   saved by the DAEFUN function and made accessible to PSETFUN.

IVP Problem

   The function PSETFUN must be defined as
        FUNCTION FLAG = PSETFUN(T,YY,YP,RR,CJ)
   If successful, it must return FLAG=0. For a recoverable error (in
   which case the setup will be retried) it must set FLAG to a positive
   integer value. If an unrecoverable error occurs, it must set FLAG
   to a negative value, in which case the integration will be halted.
   The input argument RR contains the current value of f(t,yy,yp).

   If a user data structure DATA was specified in IDAMalloc, then
   PSETFUN must be defined as
        FUNCTION [FLAG,NEW_DATA] = PSETFUN(T,YY,YP,RR,CJ,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the flags JCUR
   and FLAG, the PSETFUN function must also set NEW_DATA. Otherwise, it
   should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead
   to unnecessary copying).

Adjoint Problem
```

```
   The function PSETFUNB must be defined either as
        FUNCTION FLAG = PSETFUNB(T,YY,YP,YYB,YPB,RRB,CJB)
   or as
        FUNCTION [FLAG,NEW_DATA] = PSETFUNB(T,YY,YP,YYB,YPB,RRB,CJB,DATA)
   depending on whether a user data structure DATA was specified in
   IDAMalloc.

   See also IDAPrecSolveFn, IDASetOptions

   NOTE: PSETFUN and PSETFUNB are specified through the property
   PrecSetupFn to IDASetOptions and are used only if the property
   LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR'.
```

IDAPrecSolveFn

Purpose

```
IDAPrecSolveFn - type for user provided preconditioner solve function.
```

Synopsis

```
This is a script file.
```

Description

```
IDAPrecSolveFn - type for user provided preconditioner solve function.

   The user-supplied preconditioner solve function PSOLFUN is to solve
   a linear system P z = r, where P is the preconditioner matrix.

IVP Problem

   The function PSOLFUN must be defined as
        FUNCTION [Z, FLAG] = PSOLFUN(T,YY,YP,RR,R)
   and must return a vector Z containing the solution of Pz=r.
   If PSOLFUN was successful, it must return FLAG=0. For a recoverable
   error (in which case the step will be retried) it must set FLAG to a
   positive value. If an unrecoverable error occurs, it must set FLAG
   to a negative value, in which case the integration will be halted.
   The input argument RR contains the current value of f(t,yy,yp).

   If a user data structure DATA was specified in IDAMalloc, then
   PSOLFUN must be defined as
        FUNCTION [Z, FLAG, NEW_DATA] = PSOLFUN(T,YY,YP,RR,R,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the vector Z and
   the flag FLAG, the PSOLFUN function must also set NEW_DATA. Otherwise,
   it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would
   lead to unnecessary copying).

Adjoint Problem

   The function PSOLFUNB must be defined either as
        FUNCTION [ZB,FLAG] = PSOLFUNB(T,YY,YP,YYB,YPB,RRB,RB)
```

```
or as
     FUNCTION [ZB,FLAG,NEW_DATA] = PSOLFUNB(T,YY,YP,YYB,YPB,RRB,RB,DATA)
depending on whether a user data structure DATA was specified in
IDAMalloc. In either case, it must return the vector ZB and the
flag FLAG.

See also IDAPrecSetupFn, IDASetOptions

NOTE: PSOLFUN and PSOLFUNB are specified through the property
PrecSolveFn to IDASetOptions and are used only if the property
LinearSolver was set to 'GMRES', 'BiCGStab', or 'TFQMR'.
```

4 MATLAB Interface to KINSOL

The MATLAB interface to KINSOL provides access to all functionality of the KINSOL solver.

The interface consists of 5 user-callable functions. The user must provide several required and optional user-supplied functions which define the problem to be solved. The user-callable functions and the types of user-supplied functions are listed in Table 3 and fully documented later in this section. For more in depth details, consult also the KINSOL user guide [1].

To illustrate the use of the KINSOL MATLAB interface, several example problems are provided with SUNDIALSTB, both for serial and parallel computations. Most of them are MATLAB translations of example problems provided with KINSOL.

Table 3: KINSOL MATLAB interface functions

Functions	KINSetOptions	creates an options structure for KINSOL.
	KINMalloc	allocates and initializes memory for KINSOL.
	KINSol	solves the nonlinear problem.
	KINGetStats	returns statistics for the KINSOL solver.
	KINFree	deallocates memory for the KINSOL solver.
Function types	KINSysFn	system function
	KINDenseJacFn	dense Jacobian function
	KINBandJacFn	banded Jacobian function
	KINJacTimesVecFn	Jacobian times vector function
	KINPrecSetupFn	preconditioner setup function
	KINPrecSolveFn	preconditioner solve function
	KINGlocalFn	system approximation function (BBDPre)
	KINGcommFn	communication function (BBDPre)

4.1 Interface functions

KINSetOptions

PURPOSE

KINSetOptions creates an options structure for KINSOL.

SYNOPSIS

```
function options = KINSetOptions(varargin)
```

DESCRIPTION

KINSetOptions creates an options structure for KINSOL.

Usage:

options = KINSetOptions('NAME1',VALUE1,'NAME2',VALUE2,...) creates a KINSOL options structure options in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names.

options = KINSetOptions(oldoptions,'NAME1',VALUE1,...) alters an existing options structure oldoptions.

options = KINSetOptions(oldoptions,newoptions) combines an existing options structure oldoptions with a new options structure newoptions. Any new properties overwrite corresponding old properties.

KINSetOptions with no input arguments displays all property names and their possible values.

```
KINSetOptions properties
(See also the KINSOL User Guide)

Verbose - verbose output [ false | true ]
   Specifies whether or not KINSOL should output additional information
MaxNumIter - maximum number of nonlinear iterations [ scalar | 200 ]
   Specifies the maximum number of iterations that the nonlinar solver is allowed
   to take.
FuncRelErr - relative residual error [ scalar | eps ]
   Specifies the realative error in computing f(y) when used in difference
   quotient approximation of matrix-vector product J(y)*v.
FuncNormTol - residual stopping criteria [ scalar | eps^(1/3) ]
   Specifies the stopping tolerance on ||fscale*ABS(f(y))||_L-infinity
ScaledStepTol - step size stopping criteria [ scalar | eps^(2/3) ]
   Specifies the stopping tolerance on the maximum scaled step length:
                    ||    y_(k+1) - y_k   ||
                    || ------------------ ||_L-infinity
                    || |y_(k+1)| + yscale ||
MaxNewtonStep - maximum Newton step size [ scalar | 0.0 ]
```

```
   Specifies the maximum allowable value of the scaled length of the Newton step.
InitialSetup - initial call to linear solver setup [ false | true ]
   Specifies whether or not KINSol makes an initial call to the linear solver
   setup function.
MaxNumSetups - [ scalar | 10 ]
   Specifies the maximum number of nonlinear iterations between calls to the
   linear solver setup function (i.e. Jacobian/preconditioner evaluation)
MaxNumSubSetups - [ scalar | 5 ]
   Specifies the maximum number of nonlinear iterations between checks by the
   nonlinear residual monitoring algorithm (specifies length of subintervals).
   NOTE: MaxNumSetups should be a multiple of MaxNumSubSetups.
MaxNumBetaFails - maximum number of beta-condition failures [ scalar | 10 ]
   Specifies the maximum number of beta-condiiton failures in the line search
   algorithm.
EtaForm - Inexact Newton method [ Constant | Type2 | Type1 ]
   Specifies the method for computing the eta coefficient used in the calculation
   of the linear solver convergence tolerance (used only if strategy='InexactNEwton'
   in the call to KINSol):
      lintol = (eta + eps)*||fscale*f(y)||_L2
   which is the used to check if the following inequality is satisfied:
      ||fscale*(f(y)+J(y)*p)||_L2 &lt;= lintol
   Valid choices are:
                          | ||f(y_(k+1))||_L2 - ||f(y_k)+J(y_k)*p_k||_L2 |
   EtaForm='Type1'  eta = ----------------------------------------------
                                          ||f(y_k)||_L2

                                    [ ||f(y_(k+1))||_L2 ]^alpha
   EtaForm='Type2'  eta = gamma * [ ----------------- ]
                                    [  ||f(y_k)||_L2    ]
   EtaForm='Constant'
Eta - constant value for eta [ scalar | 0.1 ]
   Specifies the constant value for eta in the case EtaForm='Constant'.
EtaAlpha - alpha parameter for eta [ scalar | 2.0 ]
   Specifies the parameter alpha in the case EtaForm='Type2'
EtaGamma - gamma parameter for eta [ scalar | 0.9 ]
   Specifies the parameter gamma in the case EtaForm='Type2'
MinBoundEps - lower bound on eps [ false | true ]
   Specifies whether or not the value of eps is bounded below by 0.01*FuncNormtol.
Constraints - solution constraints [ vector ]
   Specifies additional constraints on the solution components.
     Constraints(i) =  0 : no constrain on y(i)
     Constraints(i) =  1 : y(i) &gt;= 0
     Constraints(i) = -1 : y(i) &lt;= 0
     Constraints(i) =  2 : y(i) &gt; 0
     Constraints(i) = -2 : y(i) &lt; 0
   If Constraints is not specified, no constraints are applied to y.

LinearSolver - Type of linear solver [ Dense | Band | GMRES | BiCGStab | TFQMR ]
   Specifies the type of linear solver to be used for the Newton nonlinear solver.
   Valid choices are: Dense (direct, dense Jacobian), GMRES (iterative, scaled
   preconditioned GMRES), BiCGStab (iterative, scaled preconditioned stabilized
   BiCG), TFQMR (iterative, scaled preconditioned transpose-free QMR).
   The GMRES, BiCGStab, and TFQMR are matrix-free linear solvers.
JacobianFn - Jacobian function [ function ]
```

```
   This propeerty is overloaded. Set this value to a function that returns
   Jacobian information consistent with the linear solver used (see Linsolver).
   If not specified, KINSOL uses difference quotient approximations.
   For the Dense linear solver, JacobianFn must be of type KINDenseJacFn and must
   return a dense Jacobian matrix. For the iterative linear solvers, GMRES,
   BiCGStab, or TFQMR, JacobianFn must be of type KINJactimesVecFn and must return
   a Jacobian-vector product.
KrylovMaxDim - Maximum number of Krylov subspace vectors [ scalar | 10 ]
   Specifies the maximum number of vectors in the Krylov subspace. This property
   is used only if an iterative linear solver, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver).
MaxNumRestarts - Maximum number of GMRES restarts [ scalar | 0 ]
   Specifies the maximum number of times the GMRES (see LinearSolver) solver
   can be restarted.
PrecModule - Built-in preconditioner module [ BBDPre | UserDefined ]
   If the PrecModule = 'UserDefined', then the user must provide at least a
   preconditioner solve function (see PrecSolveFn)
   KINSOL provides a built-in preconditioner module, BBDPre which can only be used
   with parallel vectors. It provide a preconditioner matrix that is block-diagonal
   with banded blocks. The blocking corresponds to the distribution of the variable
   vector among the processors. Each preconditioner block is generated from the
   Jacobian of the local part (on the current processor) of a given function g(t,y)
   approximating f(y) (see GlocalFn). The blocks are generated by a difference
   quotient scheme on each processor independently. This scheme utilizes an assumed
   banded structure with given half-bandwidths, mldq and mudq (specified through
   LowerBwidthDQ and UpperBwidthDQ, respectively). However, the banded Jacobian
   block kept by the scheme has half-bandwiths ml and mu (specified through
   LowerBwidth and UpperBwidth), which may be smaller.
PrecSetupFn - Preconditioner setup function [ function ]
   PrecSetupFn specifies an optional function which, together with PrecSolve,
   defines a right preconditioner matrix which is an aproximation
   to the Newton matrix. PrecSetupFn must be of type KINPrecSetupFn.
PrecSolveFn - Preconditioner solve function [ function ]
   PrecSolveFn specifies an optional function which must solve a linear system
   Pz = r, for given r. If PrecSolveFn is not defined, the no preconditioning will
   be used. PrecSolveFn must be of type KINPrecSolveFn.
GlocalFn - Local right-hand side approximation funciton for BBDPre [ function ]
   If PrecModule is BBDPre, GlocalFn specifies a required function that
   evaluates a local approximation to the system function. GlocalFn must
   be of type KINGlocalFn.
GcommFn - Inter-process communication function for BBDPre [ function ]
   If PrecModule is BBDPre, GcommFn specifies an optional function
   to perform any inter-process communication required for the evaluation of
   GlocalFn. GcommFn must be of type KINGcommFn.
LowerBwidth - Jacobian/preconditioner lower bandwidth [ scalar | 0 ]
   This property is overloaded. If the Band linear solver is used (see LinSolver),
   it specifies the lower half-bandwidth of the band Jacobian approximation.
   If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver) and if the BBDPre preconditioner module in KINSOL is used
   (see PrecModule), it specifies the lower half-bandwidth of the retained
   banded approximation of the local Jacobian block.
   LowerBwidth defaults to 0 (no sub-diagonals).
UpperBwidth - Jacobian/preconditioner upper bandwidth [ scalar | 0 ]
   This property is overloaded. If the Band linear solver is used (see LinSolver),
```

```
   it specifies the upper half-bandwidth of the band Jacobian approximation.
   If one of the three iterative linear solvers, GMRES, BiCGStab, or TFQMR is used
   (see LinSolver) and if the BBDPre preconditioner module in KINSOL is used
   (see PrecModule), it specifies the upper half-bandwidth of the retained
   banded approximation of the local Jacobian block.
   UpperBwidth defaults to 0 (no super-diagonals).
LowerBwidthDQ - BBDPre preconditioner DQ lower bandwidth [ scalar | 0 ]
   Specifies the lower half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).
UpperBwidthDQ - BBDPre preconditioner DQ upper bandwidth [ scalar | 0 ]
   Specifies the upper half-bandwidth used in the difference-quotient Jacobian
   approximation for the BBDPre preconditioner (see PrecModule).

        KINPrecSetupFn, KINPrecSolveFn
        KINGlocalFn, KINGcommFn
```

KINMalloc

Purpose

KINMalloc allocates and initializes memory for KINSOL.

Synopsis

```
function [] = KINMalloc(fct,n,varargin)
```

Description

KINMalloc allocates and initializes memory for KINSOL.

```
   Usage:   KINMalloc ( SYSFUN, N [, OPTIONS [, DATA] ] );

   SYSFUN   is a function defining the nonlinear problem f(y) = 0.
            This function must return a column vector FY containing the
            current value of the residual
   N        is the (local) problem dimension.
   OPTIONS  is an (optional) set of integration options, created with
            the KINSetOptions function.
   DATA     is the (optional) problem data passed unmodified to all
            user-provided functions when they are called. For example,
            RES = SYSFUN(Y,DATA).

   See also: KINSysFn
```

KINSol

Purpose

KINSol solves the nonlinear problem.

Synopsis

```
function [status,y] = KINSol(y0, strategy, yscale, fscale)
```

Description

```
KINSol solves the nonlinear problem.

   Usage:  [STATUS, Y] = KINSol(Y0, STRATEGY, YSCALE, FSCALE)

   KINSol manages the computational process of computing an approximate
   solution of the nonlinear system. If the initial guess (initial value
   assigned to vector Y0) doesn't violate any user-defined constraints,
   then KINSol attempts to solve the system f(y)=0. If an iterative linear
   solver was specified (see KINSetOptions), KINSol uses a nonlinear Krylov
   subspace projection method. The Newton-Krylov iterations are stopped
   if either of the following conditions is satisfied:

       ||f(y)||_L-infinity &lt;= 0.01*fnormtol

       ||y[i+1] - y[i]||_L-infinity &lt;= scsteptol

   However, if the current iterate satisfies the second stopping
   criterion, it doesn't necessarily mean an approximate solution
   has been found since the algorithm may have stalled, or the
   user-specified step tolerance may be too large.

   STRATEGY specifies the global strategy applied to the Newton step if it is
   unsatisfactory. Valid choices are 'None' or 'LineSearch'.
   YSCALE is a vector containing diagonal elements of scaling matrix for vector
   Y chosen so that the components of YSCALE*Y (as a matrix multiplication) all
   have about the same magnitude when Y is close to a root of f(y)
   FSCALE is a vector containing diagonal elements of scaling matrix for f(y)
   chosen so that the components of FSCALE*f(Y) (as a matrix multiplication)
   all have roughly the same magnitude when u is not too near a root of f(y)

   On return, status is one of the following:
     0: KINSol succeeded
     1: The initial y0 already satisfies the stopping criterion given above
     2: Stopping tolerance on scaled step length satisfied
    -1: Illegal attempt to call before KINMalloc
    -2: One of the inputs to KINSol is illegal.
    -5: The line search algorithm was unable to find an iterate sufficiently
        distinct from the current iterate
    -6: The maximum number of nonlinear iterations has been reached
    -7: Five consecutive steps have been taken that satisfy the following
        inequality:
             ||yscale*p||_L2 &gt; 0.99*mxnewtstep
    -8: The line search algorithm failed to satisfy the beta-condition
        for too many times.
    -9: The linear solver's solve routine failed in a recoverable manner,
        but the linear solver is up to date.
   -10: The linear solver's intialization routine failed.
   -11: The linear solver's setup routine failed in an unrecoverable manner.
   -12: The linear solver's solve routine failed in an unrecoverable manner.

   See also KINSetOptions, KINGetstats
```

KINGetStats

Purpose

KINGetStats returns statistics for the main KINSOL solver and the linear

Synopsis

```
function si = KINGetStats()
```

Description

```
KINGetStats returns statistics for the main KINSOL solver and the linear
solver used.

   Usage: solver_stats = KINGetStats;

Fields in the structure solver_stats

o nfe    - total number evaluations of the nonlinear system function SYSFUN
o nni    - total number of nonlinear iterations
o nbcf   - total number of beta-condition failures
o nbops  - total number of backtrack operations (step length adjustments)
           performed by the line search algorithm
o fnorm  - scaled norm of the nonlinear system function f(y) evaluated at the
           current iterate: ||fscale*f(y)||_L2
o step   - scaled norm (or length) of the step used during the previous
           iteration: ||uscale*p||_L2
o LSInfo - structure with linear solver statistics

The structure LSinfo has different fields, depending on the linear solver used.

  Fields in LSinfo for the 'Dense' linear solver

o name - 'Dense'
o njeD - number of Jacobian evaluations
o nfeD - number of right-hand side function evaluations for difference-quotient
         Jacobian approximation

  Fields in LSinfo for the 'GMRES' or 'BiCGStab' linear solver

o name - 'GMRES' or 'BiCGStab'
o nli  - number of linear solver iterations
o npe  - number of preconditioner setups
o nps  - number of preconditioner solve function calls
o ncfl - number of linear system convergence test failures
```

KINFree

Purpose

KINFree deallocates memory for the KINSOL solver.

Synopsis

```
function [] = KINFree()
```

Description

KINFree deallocates memory for the KINSOL solver.

Usage: KINFree

4.2 Function types

KINDenseJacFn

PURPOSE

KINDenseJacFn - type for user provided dense Jacobian function.

SYNOPSIS

This is a script file.

DESCRIPTION

KINDenseJacFn - type for user provided dense Jacobian function.

```
   The function DJACFUN must be defined as
        FUNCTION [J, FLAG] = DJACFUN(Y,FY)
   and must return a matrix J corresponding to the Jacobian of f(y).
   The input argument FY contains the current value of f(y).
   If a user data structure DATA was specified in KINMalloc, then
   DJACFUN must be defined as
        FUNCTION [J, FLAG, NEW_DATA] = DJACFUN(Y,FY,DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix J and
   the flag FLAG, the DJACFUN function must also set NEW_DATA. Otherwise,
   it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead
   to unnecessary copying).

   The function DJACFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also KINSetOptions

   NOTE: DJACFUN is specified through the property JacobianFn to KINSetOptions
   and is used only if the property LinearSolver was set to 'Dense'.
```

KINBandJacFn

PURPOSE

KINBandJacFn - type for user provided banded Jacobian function.

SYNOPSIS

This is a script file.

DESCRIPTION

```
KINBandJacFn - type for user provided banded Jacobian function.

   The function BJACFUN must be defined as
        FUNCTION [J, FLAG] = BJACFUN(Y, FY)
   and must return a matrix J corresponding to the banded Jacobian of f(y).
   The input argument FY contains the current value of f(y).
   If a user data structure DATA was specified in KINMalloc, then
   BJACFUN must be defined as
        FUNCTION [J, FLAG, NEW_DATA] = BJACFUN(Y, FY, DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the matrix J and
   the flag FLAG, the BJACFUN function must also set NEW_DATA. Otherwise,
   it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead
   to unnecessary copying).

   The function BJACFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.

   See also KINSetOptions

   NOTE: BJACFUN is specified through the property JacobianFn to KINSetOptions
   and is used only if the property LinearSolver was set to 'Band'.
```

KINGcommFn

Purpose

```
KINGcommFn - type for user provided communication function (BBDPre).
```

Synopsis

```
This is a script file.
```

Description

```
KINGcommFn - type for user provided communication function (BBDPre).

   The function GCOMFUN must be defined as
        FUNCTION FLAG = GCOMFUN(Y)
   and can be used to perform all interprocess communication necessary
   to evaluate the approximate right-hand side function for the BBDPre
   preconditioner module.
   If a user data structure DATA was specified in KINMalloc, then
   GCOMFUN must be defined as
        FUNCTION [FLAG, NEW_DATA] = GCOMFUN(Y, DATA)
   If the local modifications to the user data structure are needed
   in other user-provided functions then the GCOMFUN function must also
   set NEW_DATA. Otherwise, it should set NEW_DATA=[] (do not set
   NEW_DATA = DATA as it would lead to unnecessary copying).

   The function GCOMFUN must set FLAG=0 if successful, FLAG&lt;0 if an
   unrecoverable failure occurred, or FLAG&gt;0 if a recoverable error
   occurred.
```

See also KINGlocalFn, KINSetOptions

NOTES:
GCOMFUN is specified through the GcommFn property in KINSetOptions
and is used only if the property PrecModule is set to 'BBDPre'.

Each call to GCOMFUN is preceded by a call to the system function
SYSFUN with the same argument Y. Thus GCOMFUN can omit any communication
done by SYSFUN if relevant to the evaluation of G by GLOCFUN. If all
necessary communication was done by SYSFUN, GCOMFUN need not be provided.

KINGlocalFn

Purpose

KINGlocalFn - type for user provided RHS approximation function (BBDPre).

Synopsis

This is a script file.

Description

KINGlocalFn - type for user provided RHS approximation function (BBDPre).

The function GLOCFUN must be defined as
```
     FUNCTION [G, FLAG] = GLOCFUN(Y)
```
and must return a vector G corresponding to an approximation to f(y)
which will be used in the BBDPRE preconditioner module. The case where
G is mathematically identical to F is allowed.
If a user data structure DATA was specified in KINMalloc, then
GLOCFUN must be defined as
```
     FUNCTION [G, FLAG, NEW_DATA] = GLOCFUN(Y, DATA)
```
If the local modifications to the user data structure are needed
in other user-provided functions then, besides setting the vector G,
the GLOCFUN function must also set NEW_DATA. Otherwise, it should set
NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
unnecessary copying).

The function GLOCFUN must set FLAG=0 if successful, FLAG<0 if an
unrecoverable failure occurred, or FLAG>0 if a recoverable error
occurred.

See also KINGcommFn, KINSetOptions

NOTE: GLOCFUN is specified through the GlocalFn property in KINSetOptions
and is used only if the property PrecModule is set to 'BBDPre'.

KINJacTimesVecFn

PURPOSE

KINJacTimesVecFn - type for user provided Jacobian times vector function.

SYNOPSIS

This is a script file.

DESCRIPTION

KINJacTimesVecFn - type for user provided Jacobian times vector function.

```
   The function JTVFUN must be defined as
        FUNCTION [JV, NEW_Y, FLAG] = JTVFUN(Y, V, NEW_Y)
   and must return a vector JV corresponding to the product of the
   Jacobian of f(y) with the vector v. On input, NEW_Y indicates if
   the iterate has been updated in the interim. JV must be update
   or reevaluated, if appropriate, unless NEW_Y=false. This flag must
   be reset by the user.
   If a user data structure DATA was specified in KINMalloc, then
   JTVFUN must be defined as
        FUNCTION [JV, NEW_Y, FLAG, NEW_DATA] = JTVFUN(Y, V, NEW_Y, DATA)
   If the local modifications to the user data structure are needed in
   other user-provided functions then, besides setting the vector JV, and
   flags NEW_Y and FLAG, the JTVFUN function must also set NEW_DATA. Otherwise,
   it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
   unnecessary copying).

   If successful, FLAG should be set to 0. If an error occurs, FLAG should
   be set to a nonzero value.

   See also KINSetOptions

   NOTE: JTVFUN is specified through the property JacobianFn to KINSetOptions
   and is used only if the property LinearSolver was set to 'GMRES' or 'BiCGStab'.
```

KINPrecSetupFn

PURPOSE

KINPrecSetupFn - type for user provided preconditioner setup function.

SYNOPSIS

This is a script file.

DESCRIPTION

KINPrecSetupFn - type for user provided preconditioner setup function.

```
   The user-supplied preconditioner setup subroutine should compute
   the right-preconditioner matrix P used to form the scaled preconditioned
   linear system:

   (Df*J(y)*(P^-1)*(Dy^-1)) * (Dy*P*x) = Df*(-F(y))
```

```
where Dy and Df denote the diagonal scaling matrices whose diagonal elements
are stored in the vectors YSCALE and FSCALE, respectively.

The preconditioner setup routine (referenced by iterative linear
solver modules via pset (type KINSpilsPrecSetupFn)) will not be
called prior to every call made to the psolve function, but will
instead be called only as often as necessary to achieve convergence
of the Newton iteration.

NOTE: If the PRECSOLVE function requires no preparation, then a
preconditioner setup function need not be given.

The function PSETFUN must be defined as
     FUNCTION FLAG = PSETFUN(Y, YSCALE, FY, FSCALE)
The input argument FY contains the current value of f(y), while YSCALE
and FSCALE are the scaling vectors for solution and system function,
respectively (as passed to KINSol)

If a user data structure DATA was specified in KINMalloc, then
PSETFUN must be defined as
     FUNCTION [FLAG, NEW_DATA] = PSETFUN(Y, YSCALE, FY, FSCALE, DATA)
If the local modifications to the user data structure are needed in
other user-provided functions then, besides setting the flag FLAG,
the PSETFUN function must also set NEW_DATA. Otherwise, it should
set NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead
to unnecessary copying).

If successful, PSETFUN must return FLAG=0. For a recoverable error (in
which case the setup will be retried) it must set FLAG to a positive
integer value. If an unrecoverable error occurs, it must set FLAG
to a negative value, in which case the solver will halt.

See also KINPrecSolveFn, KINSetOptions, KINSol

NOTE: PSETFUN is specified through the property PrecSetupFn to KINSetOptions
and is used only if the property LinearSolver was set to 'GMRES' or 'BiCGStab'.
```

KINPrecSolveFn

Purpose

```
KINPrecSolveFn - type for user provided preconditioner solve function.
```

Synopsis

```
This is a script file.
```

Description

```
KINPrecSolveFn - type for user provided preconditioner solve function.

   The user-supplied preconditioner solve function PSOLFN
   is to solve a linear system P z = r in which the matrix P is
```

```
the preconditioner matrix (possibly set implicitely by PSETFUN)

The function PSOLFUN must be defined as
     FUNCTION [Z, FLAG] = PSOLFUN(Y, YSCALE, FY, FSCALE, R)
and must return a vector Z containing the solution of Pz=r.
The input argument FY contains the current value of f(y), while YSCALE
and FSCALE are the scaling vectors for solution and system function,
respectively (as passed to KINSol)

If a user data structure DATA was specified in KINMalloc, then
PSOLFUN must be defined as
     FUNCTION [Z, FLAG, NEW_DATA] = PSOLFUN(Y,YSCALE,FY,FSCALE,R,DATA)
If the local modifications to the user data structure are needed in
other user-provided functions then, besides setting the vector Z and
the flag FLAG, the PSOLFUN function must also set NEW_DATA. Otherwise,
it should set NEW_DATA=[] (do not set NEW_DATA = DATA as it would
lead to unnecessary copying).

If successful, PSOLFUN must return FLAG=0. For a recoverable error it
must set FLAG to a positive value (in which case the solver will attempt
to correct). If an unrecoverable error occurs, it must set FLAG
to a negative value, in which case the solver will halt.

See also KINPrecSetupFn, KINSetOptions

NOTE: PSOLFUN is specified through the property PrecSolveFn to KINSetOptions
and is used only if the property LinearSolver was set to 'GMRES' or 'BiCGStab'.
```

KINSysFn

Purpose

```
KINSysFn - type for user provided system function
```

Synopsis

```
This is a script file.
```

Description

```
KINSysFn - type for user provided system function

The function SYSFUN must be defined as
     FUNCTION [FY, FLAG] = SYSFUN(Y)
and must return a vector FY corresponding to f(y).
If a user data structure DATA was specified in KINMalloc, then
SYSFUN must be defined as
     FUNCTION [FY, FLAG, NEW_DATA] = SYSFUN(Y,DATA)
If the local modifications to the user data structure are needed
in other user-provided functions then, besides setting the vector FY,
the SYSFUN function must also set NEW_DATA. Otherwise, it should set
NEW_DATA=[] (do not set NEW_DATA = DATA as it would lead to
unnecessary copying).
```

The function SYSFUN must set FLAG=0 if successful, FLAG<0 if an unrecoverable failure occurred, or FLAG>0 if a recoverable error occurred.

See also KINMalloc

NOTE: SYSFUN is specified through the KINMalloc function.

5 Supporting modules

This section describes two additional modules in SUNDIALSTB, NVECTOR and PUTILS. The functions in NVECTOR perform various operations on vectors. For serial vectors, all of these operations default to the corresponding MATLAB functions. For parallel vectors, they can be used either on the local portion of the distributed vector or on the global vector (in which case they will trigger an MPI Allreduce operation). The functions in PUTILS are used to run parallel SUNDIALSTB applications. The user should only call the function `mpirun` to launch a parallel MATLAB application. See one of the paralel SUNDIALSTB examples for usage.

The functions in these two additional modules are listed in Table 4 and described in detail in the remainder of this section.

Table 4: The NVECTOR and PUTILS functions

NVECTOR	N_VMax	returns the largest element of x
	N_VMaxNorm	returns the maximum norm of x
	N_VMin	returns the smallest element of x
	N_VDotProd	returns the dot product of two vectors
	N_VWrmsNorm	returns the weighted root mean square norm of x
	N_VWL2Norm	returns the weighted Euclidean L2 norm of x
	N_VL1Norm	returns the L1 norm of x
PUTILS	mpirun	runs parallel examples
	mpiruns	runs the parallel example on a child MATLAB process
	mpistart	lamboot and `MPI_Init` master (if required)

5.1 NVECTOR functions

N_VDotProd

PURPOSE

N_VDotProd returns the dot product of two vectors

SYNOPSIS

```
function ret = N_VDotProd(x,y,comm)
```

DESCRIPTION

```
N_VDotProd returns the dot product of two vectors

   Usage:  RET = N_VDotProd ( X, Y [, COMM] )

If COMM is not present, N_VDotProd returns the dot product of the
local portions of X and Y. Otherwise, it returns the global dot
product.
```

SOURCE CODE

```
function ret = N_VDotProd(x,y,comm)

% Radu Serban <radu@llnl.gov>
% Copyright (c) 2005, The Regents of the University of California.
% $Revision: 1.1 $Date: 2006/01/06 19:00:10 $

if nargin == 2

  ret = dot(x,y);

else

  ldot = dot(x,y);
  gdot = 0.0;
  MPI_Allreduce(ldot,gdot,'SUM',comm);
  ret = gdot;

end
```

N_VL1Norm

PURPOSE

N_VL1Norm returns the L1 norm of x

SYNOPSIS

```
function ret = N_VL1Norm(x,comm)
```

DESCRIPTION

N_VL1Norm returns the L1 norm of x

```
   Usage:  RET = N_VL1Norm ( X [, COMM] )
```

If COMM is not present, N_VL1Norm returns the L1 norm of
the local portion of X. Otherwise, it returns the global
L1 norm..

SOURCE CODE

```
function ret = N_VL1Norm(x,comm)

% Radu Serban <radu@llnl.gov>
% Copyright (c) 2005, The Regents of the University of California.
% $Revision: 1.1 $Date: 2006/01/06 19:00:10 $

if nargin == 1

  ret = norm(x,1);

else

  lnrm = norm(x,1);
  gnrm = 0.0;
  MPI_Allreduce(lnrm,gnrm,'MAX',comm);
  ret = gnrm;

end
```

N_VMax

PURPOSE

N_VMax returns the largest element of x

SYNOPSIS

```
function ret = N_VMax(x,comm)
```

DESCRIPTION

N_VMax returns the largest element of x

```
   Usage:  RET = N_VMax ( X [, COMM] )
```

If COMM is not present, N_VMax returns the maximum value of
the local portion of X. Otherwise, it returns the global
maximum value.

SOURCE CODE

```
function ret = N_VMax(x,comm)

% Radu Serban <radu@llnl.gov>
% Copyright (c) 2005, The Regents of the University of California.
% $Revision: 1.1 $Date: 2006/01/06 19:00:10 $
```

```
13
14 if nargin == 1
15
16   ret = max(x);
17
18 else
19
20   lmax = max(x);
21   gmax = 0.0;
22   MPI_Allreduce(lmax,gmax,'MAX',comm);
23   ret = gmax;
24
25 end
```

N_VMaxNorm

Purpose

N_VMaxNorm returns the L-infinity norm of x

Synopsis

```
function ret = N_VMaxNorm(x, comm)
```

Description

N_VMaxNorm returns the L-infinity norm of x

```
   Usage:  RET = N_VMaxNorm ( X [, COMM] )
```

If COMM is not present, N_VMaxNorm returns the L-infinity norm
of the local portion of X. Otherwise, it returns the global
L-infinity norm..

Source Code

```
1  function ret = N_VMaxNorm(x, comm)
9
10 % Radu Serban <radu@llnl.gov>
11 % Copyright (c) 2005, The Regents of the University of California.
12 % $Revision: 1.1 $Date: 2006/01/06 19:00:10 $
13
14 if nargin == 1
15
16   ret = norm(x,'inf');
17
18 else
19
20   lnrm = norm(x,'inf');
21   gnrm = 0.0;
22   MPI_Allreduce(lnrm,gnrm,'MAX',comm);
23   ret = gnrm;
24
25 end
```

N_VMin

Purpose

N_VMin returns the smallest element of x

Synopsis

```
function ret = N_VMin(x,comm)
```

Description

```
N_VMin returns the smallest element of x
   Usage:  RET = N_VMin ( X [, COMM] )

If COMM is not present, N_VMin returns the minimum value of
the local portion of X. Otherwise, it returns the global
minimum value.
```

Source Code

```
function ret = N_VMin(x,comm)

% Radu Serban <radu@llnl.gov>
% Copyright (c) 2005, The Regents of the University of California.
% $Revision: 1.1 $Date: 2006/01/06 19:00:10 $

if nargin == 1

  ret = min(x);

else

  lmin = min(x);
  gmin = 0.0;
  MPI_Allreduce(lmin,gmin,'MIN',comm);
  ret = gmin;

end
```

N_VWL2Norm

Purpose

N_VWL2Norm returns the weighted Euclidean L2 norm of x

Synopsis

```
function ret = N_VWL2Norm(x,w,comm)
```

Description

```
N_VWL2Norm returns the weighted Euclidean L2 norm of x
   with weight vector w:
   sqrt [(sum (i = 0 to N-1) (x[i]*w[i])^2)]

   Usage:  RET = N_VWL2Norm ( X, W [, COMM] )

If COMM is not present, N_VWL2Norm returns the weighted L2
norm of the local portion of X. Otherwise, it returns the
global weighted L2 norm..
```

SOURCE CODE

if nargin == 2

  ret = dot(x.^2,w.^2);
  ret = sqrt(ret);

else

  lnrm = dot(x.^2,w.^2);
  gnrm = 0.0;
  MPI_Allreduce(lnrm,gnrm,'SUM',comm);

  ret = sqrt(gnrm);

end
```

N_VWrmsNorm

PURPOSE

```
N_VWrmsNorm returns the weighted root mean square norm of x
```

SYNOPSIS

```
function ret = N_VWrmsNorm(x,w,comm)
```

DESCRIPTION

```
N_VWrmsNorm returns the weighted root mean square norm of x
with weight vector w:
   sqrt [(sum (i = 0 to N-1) (x[i]*w[i])^2)/N]

   Usage:  RET = N_VWrmsNorm ( X, W [, COMM] )

If COMM is not present, N_VWrmsNorm returns the WRMS norm
of the local portion of X. Otherwise, it returns the global
WRMS norm..
```

SOURCE CODE

function ret = N_VWrmsNorm(x,w,comm)

% Radu Serban <radu@llnl.gov>
% Copyright (c) 2005, The Regents of the University of California.
% $Revision: 1.1 $Date: 2006/01/06 19:00:11 $

if nargin == 2

  ret = dot(x.^2,w.^2);
  ret = sqrt(ret/length(x));

else

  lnrm = dot(x.^2,w.^2);
  gnrm = 0.0;
  MPI_Allreduce(lnrm,gnrm,'SUM',comm);

  ln = length(x);
  gn = 0;
  MPI_Allreduce(ln,gn,'SUM',comm);

  ret = sqrt(gnrm/gn);

end
```

5.2 Parallel utilities

---

mpirun

PURPOSE

MPIRUN runs parallel examples.

SYNOPSIS

```
function [] = mpirun(fct,npe,dbg)
```

DESCRIPTION

```
MPIRUN runs parallel examples.

  Usage: MPIRUN ( FCT , NPE [, DBG] )

  FCT - function to be executed on all MATLAB processes.
  NPE - number of processes to be used (including the master).
  DBG - flag for debugging [ true | false ]
        If true, spawn MATLAB child processes with a visible xterm.
```

SOURCE CODE

```

mpiruns

Purpose

```
MPIRUNS runs the parallel example on a child MATLAB process.
```

Synopsis

```
function [] = mpiruns(fct)
```

Description

```
MPIRUNS runs the parallel example on a child MATLAB process.

  Usage: MPIRUNS ( FCT )

  This function should not be called directly. It is called
  by mpirun on the spawned child processes.
```

Source Code

```
1 function [] = mpiruns(fct)

mpistart

Purpose

MPISTART invokes lamboot (if required) and MPI_Init (if required).

Synopsis

function mpistart(nslaves, rpi, hosts)

Description

```
MPISTART invokes lamboot (if required) and MPI_Init (if required).

   Usage: MPISTART [ ( NSLAVES [, RPI [, HOSTS] ] ) ]

   MPISTART boots LAM and initializes MPI to match a given number of slave
   hosts (and rpi) from a given list of hosts. All three args optional.

   If they are not defined, HOSTS are taken from a builtin HOSTS list
   (edit HOSTS at the beginning of this file to match your cluster)
   or from the bhost file if defined through LAMBHOST (in this order).

   If not defined, RPI is taken from the builtin variable RPI (edit it
   to suit your needs) or from the LAM_MPI_SSI_rpi environment variable
   (in this order).
```

Source Code

```
